414 Nevertheless, human, when you cannot embrace the causes of things, does not scruple to insist that they are impossible to be the production of Nature, 415 although you are entirely ignorant how far the powers of this Nature extend; to what Her capabilities are equal. 416 In viewing the world, we must acknowledge material causes for many of those phenomena which take place in it; 417 those who study Nature are continually adding fresh discoveries to this list of physical causes; 418 science, as She enriches the intellectual stores of human enjoyment, every day throws a broader light on the energies of Nature, 419 which prejudice, aided by its almost inseparable companion, ignorance, would forever bind down in the fetters of impotence.

420 Let us not, however, be told, that pursuing this hypothesis, we attribute everything to a blind cause-- to the fortuitous concurrence of atoms-- to chance. 421 Those only are called blind causes of which we know not either the combination, the laws, or the power. 422 Those effects are

called fortuitous, with whose causes human is unacquainted; 423 to which your experience affords you no clue; which your ignorance prevents you from foreseeing. 424 All those effects, of which you does not see the necessary connection with their causes, you attributes to chance. 425 Nature is not a blind cause; She never acts by chance; 426 nothing that She does would ever be considered fortuitous, by you who should understand Her mode of action-- who had a knowledge of Her resources-- who was intelligent in Her ways. 427 Everything that She produces is strictly necessary-- is never more than a consequence of Her eternal, immutable laws; all is connected in Her by invisible bonds; 428 every effect we witness flows necessarily from the cause of Nature, whether we are in a condition to fathom it, or whether we are obliged to let it remain hidden from our view.

429 It is very possible there should be ignorance on our part; but the words spirit, intelligence, will not remedy this ignorance; they will rather redouble it, by arresting our research; 430 by preventing us from conquering those impediments which obstruct us in probing the natural causes of the effects, with which our visual faculties bring us acquainted. 431 This may serve for an answer to the clamour of those who raise perpetual objections to the partisans of Nature, by unceasingly accusing them with attributing everything to chance.

432 Chance is a word devoid of sense, which furnishes no substantive idea; at least it indicates only the ignorance of its employers. 433 Nevertheless, we are triumphantly told, it is reiterated continually, that a regular work cannot be ascribed to the concurrence of chance. 434 Never, we are informed, will it be possible to arrive at the formation of a poem such as the Iliad, 435 by means of letters thrown together promiscuously or combined at random. 436 We agree to it without hesitation; but, ingenuously, are the letters which compose a poem thrown with the hand in the manner of dice? 437 It would avail as much to

say, we could not pronounce a discourse with the feet.

438 It is Nature, who combines according to necessary laws, under given circumstances, a head organised in a mode suitable to bring forth a poem: 439 it is Nature who assembles the elements, which furnish human with a brain competent to give birth to such a work: 440 it is Nature, who, through the medium of the imagination, by means of the passions, 441 in consequence of the temperament which She bestows upon human, capacitates you to produce such a masterpiece of fancy; such a never-fading effort of the mind: 442 it is your brain modified in a certain manner, crowded with ideas, decorated with images, made fruitful by circumstances, 443 that alone can become the matrix in which a poem can be conceived-- in which the matter of it can be digested: 444 this is the only womb whose activity could usher to an admiring world, the sublime stanzas which developed the story of the unfortunate Priam, and immortalise their author. 445 A head organised like that of Homer, furnished with the same vigour, glowing with the same vivid imagination, enriched with the same erudition, 446 placed under the same circumstances, would necessarily, and not by chance, produce the poem of the Iliad; 447 at least, unless it be denied that causes similar in everything must produce effects perfectly identical.

448 We should without doubt be surprised, if there were in a dice-box a hundred thousand dice, to see a hundred thousand sixes follow in succession; 449 but if these dice were all cogged or loaded, our surprise would cease: 450 the particles of matter may be compared to cogged dice, that is to say, always producing certain determinate effects under certain given circumstances; 451 these particles being essentially varied in themselves, countless in their combinations, they are cogged in myriads of different modes. 452 The head of Homer, or of Virgil, was no more than an assemblage of particles, possessing peculiar properties; 453 or if they will, of dice

cogged by Nature; that is to say, of beings so combined, of matter so wrought, as to produce the beautiful poems of the Iliad or the Aeneid. 454 As much may be said of all other productions: indeed, what are humans themselves but cogged dice--machines into which Nature has infused the bias requisite to produce effects of a certain description? 455 A person of genius produces a good work, in the same manner as a tree of a good species, placed in a prolific soil, cultivated with care, grafted with judgment, produces excellent fruit.

456 Then is it not either knavery or puerility, to talk of composing a work by scattering letters with the hand; by promiscuously mingling characters; 457 or gathering together by chance, that which can only result from a human brain, with a peculiar organisation, modified after a certain manner? 458 The principle of human generation does not develop itself by chance; 459 it cannot be nourished with effect, expanded into life, but in the womb of a woman: 460 a confused heap of characters, a jumble of symbols, is nothing more than an assemblage of signs, whose proper arrangement is adequate to paint human ideas; 461 but in order that these ideas may be correctly delineated, it is previously requisite that they should have been conceived, combined, nourished, connected, 462 band developed in the brain of a poet; where circumstances make them fructify, mature them, and bring them forth in perfection, 463 by reason of the fecundity, generated by the genial warmth and the peculiar energy of the matrix, in which these intellectual seeds shall have been placed.

464 Ideas in combining, expanding, connecting, and associating themselves, form a whole, like all the other bodies of Nature: 465 this whole affords us pleasure, becomes a source of enjoyment, when it gives birth to agreeable sensations in the mind; 466 when it offers to our examination pictures calculated to move us in a lively manner. 467 It is thus that the history of the Trojan war, as digested in the head of Homer, ushered into the world with

all the fascinating harmony of numbers peculiar to himself, 468 has the power of giving a pleasurable impulse to heads, who by their analogy with that of this incomparable Grecian, are in a capacity to feel its beauties.

469 From this it will be obvious, that nothing can be produced by chance; 470 that no effect can exist without an adequate cause for its existence; that the one must ever be commensurate with the other. 471 All the works of Nature grow out of the uniform action of invariable laws, 472 whether our mind can with facility follow the concatenation of the successive causes which operate; 473 or whether, as in Her more complicated productions, we find ourselves in the impossibility of distinguishing the various springs which She sets in motion to give birth to Her phenomena. 474 To Nature, the difficulty is not more to produce a great poet, capable of writing an admirable poem, 475 than to form a glittering stone or a shining metal which gravitates towards a centre. 476 The mode She adopts to give birth to these various beings, is equally unknown to us, when we have not meditated upon it; 477 frequently the most sedulous attention, the most patient investigation affords us no information; 478 sometimes, however, the unwearied industry of the philosopher is rewarded, by throwing into light the most mysterious operations.

479 Thus the keen penetration of a Newton, aided by uncommon diligence, developed the starry system, 480 which, for so many thousand years, had eluded the research of all the astronomers by whom he was preceded. 481 Thus the sagacity of a Harvey giving vigour to his application, brought out of the obscurity in which for almost countless centuries it had been buried, 482 the true course pursued by the sanguinary fluid, when circulating through the veins and arteries of human, 483 giving activity to your machine, diffusing life through your system, and enabling you to perform those actions which

so frequently strike an astonished world with wonder and regret.

484 Thus Gallileo, by a quickness of perception, a depth of reasoning peculiar to himself, held up to an admiring world, the actual form and situation of the planet we inhabit; 485 which until then had escaped the observation of the most profound geniuses-- the most subtle metaphysicians-- the whole host of priests; 486 which when first promulgated was considered so extraordinary, so contradictory to all the then received opinions, either sacred or profane, 487 that he was ranked as an atheist, as an impious blasphemer, to hold communion with whom, would secure to the communers a place in the regions of everlasting torment; 488 in short, it was held an heresy of such an indelible dye, that notwithstanding the infallibility of his sacred function, 489 Pope Gregory, who then filled the papal chair, excommunicated all those who had the temerity to accredit so abominable a doctrine.

490 Human is born by the necessary concurrence of those elements suitable to own construction; 491 you increases in bulk, corroborates your system, expands your powers, in the same manner as a plant or a stone; 492 which as well as yourself, are augmented in their volume, invigorated in their capabilities, by the addition of homogeneous matter, that exists within the sphere of their attraction. 493 Human feels, thinks, receives ideas, acts after a certain manner, that is to say, according to your organic structure, which is peculiar to yourself; 494 that renders you susceptible of modifications, of which the stone and the plant are utterly incapable.

495 On the other hand, the organisation of these beings is of a nature to enable them to receive other modifications, which human is not more capacitated to experience, 496 than the stone or the plant are those which constitute them what they are. 497 In consequence of this peculiar arrangement, the person of genius produces works of merit; 498 the plant when it is healthy yields

delicious fruits the stone when it is placed in a suitable matrix possesses a glittering brilliance which dazzles the eyes of mortals; 499 each in their sphere of action both surprise and delight us; because we feel that they excite in us sensations, that harmonise with what we call order; 500 in consequence of the pleasure they infuse, by the rarity, by the magnitude, and by the variety of the effects which they occasion us to experience.

501 Nevertheless, that which is found most admirable in the productions of Nature, 502 that which is most esteemed in the actions of human, most highly valued in animals, most sought after in vegetation, most in request among fossils, 503 is never more than the natural effects of the different particles of matter, diversely arranged, variously combined, submitted to numerous modifications; 504 from matter thus united result organs, brains, temperament, taste, talents, all the multifarious properties, 505 all the multitudinous qualities, which discriminate the beings whose multiplied activity make up the sum of what is designated animated nature.

506 Nature then produces nothing but what is necessary; 507 it is not by fortuitous combinations, by chance throws, that She exhibits to our view the beings we behold; 508 all Her throws are sure, all the causes She employs have infallibly their effects. 509 Whenever She gives birth to extraordinary, marvellous, rare beings, it is, that the requisite order of things the concurrence of the necessary productive causes, happens but seldom. 510 As soon as those beings exist, they are to be ascribed to Nature, equally with the most familiar of Her productions; 511 to Nature everything is equally possible, equally facile, when She assembles together the instruments or the causes necessary to act.

512 Thus it seems presumption in human to set limits to the powers of Nature, which you so very imperfectly understands. 513 The combinations, or if they will, the throws that She makes in an eternity of existence, can easily produce all

the beings that have existed: 514 Her eternal march must necessarily bring forth, again and again, the most astonishing circumstances; 515 the most rare occurrences; those most calculated to rouse the wonder, to elicit the admiration of beings, who are only in a condition to give them a momentary consideration; 516 who can get nothing more than a glimpse, without ever having either the leisure or the means to search into causes, 517 which lie hid from their weak eyes, in the depths of Cimmerian obscurity. 518 Countless throws during eternity, with elements and combinations varied almost to infinity, quite with relation to human, 519 suffice to produce everything of which you have a knowledge, with multitudes of other effects, of which you will never have the least conception.

520 Thus, we cannot too often repeat to the metaphysicians, to the supporters of immateriality, to the inconsistent theologians, 521 who commonly ascribe to their adversaries the most ridiculous opinions, in order to obtain an easy, short-lived triumph in the prejudiced eyes of the multitude; 522 or in the stagnant minds of those who never examine deeply; that chance is nothing but a word, 523 as well as many other words, imagined solely to cover the ignorance of those to whom the course of Nature is inexplicable-- 524 to shield the idleness of others who are too slothful to seek into the properties of acting causes. 525 It is not chance that has produced the universe, it is self-existent; 526 Nature exists necessarily from all eternity: She is omnipotent because everything is produced by Her energies; 527 She is omnipresent, because She fills all space; 528 She is omniscient, because everything can only be what it actually is; 529 She is immovable, because as a whole She cannot be displaced; 530 She is immutable, because Her essence cannot change, although Her forms may vary; 531 She is infinite, because She cannot have any bounds; 532 She is all perfect, because She contains everything: 533 in short, She has all the abstract qualities of the

metaphysician, all the moral faculties of the theologian, without involving any contradiction, 534 since that which is the assemblage of all, must of necessity contain the properties of all.

535 However concealed may be Her ways, the existence of Nature is indubitable; Her mode of action is in some respects known to us. 536 Experience amply demonstrates we might, if we were more industrious, become better acquainted with Her secrets; 537 but with an immaterial substance, with a pure spirit, the mind of human can never become familiar: 538 you have no means by which you can picture to yourself this incomprehensible, this inconceivable quality: 539 in despite therefore of the roundness of assertion adopted by the theologian, notwithstanding all the subtilties of the metaphysician, 540 it will always be for human, while you remains such as you now is, in the language of Doctor Samuel Clarke, that, of which nothing can with truth be affirmed.

OF PANTHEISM; OR OF THE NATURAL IDEAS OF THE DIVINITY

Paul Henri Thiery (Baron D'Holbach)

49 The false principle that matter is not self-existent; that by its nature it is in an impossibility to move itself; 2 consequently incompetent to the production of those striking phenomena which arrest our wondering eyes in the wide expanse of the universe; 3 it will be obvious, to all who seriously attend to what has preceded, is the origin of the proofs upon which theology rests the existence of immateriality. 4 After these suppositions, as gratuitous as they are erroneous, the fallacy of which we have exposed elsewhere, 5 it has been believed that matter did not always exist, but that its existence, as well as its motion, is a production of time; 6 due to a cause distinguished from itself; to an unknown agent to whom it is subordinate.

7 As human finds in own species a quality which you calls intelligence, which presides over all your actions, by the aid of which you arrives at the

end you proposes to yourself; 8 you have clothed this invisible agent with this quality, which you have extended beyond the limits of your own conception: 9 you magnified it thus, because, having made you the author of effects of which you found yourself incapable, 10 you did not conceive it possible that the intelligence you yourself possessed, unless it was prodigiously amplified, would be sufficient to account for those productions, 11 to which your erring judgment led you to conclude the natural energy of physical causes were not adequate.

12 As this agent was invisible, as His mode of action was inconceivable, you made Him a spirit, 13 a word that really means nothing more than that you are ignorant of His essence, 14 or that He acts like the breath of which you cannot trace the motion. 15 Thus, in speaking of spirituality, you designated an occult quality, which you deemed suitable to a concealed being, 16 whose mode of action was always imperceptible to the senses.

17 It would appear, however, that originally the word spirit was not meant to designate immateriality; 18 but a matter of a more subtile nature than that which acted coarsely on the organs: 19 still of a nature capable of penetrating the grosser matter-- of communicating to its motion-- of instilling into its active life-- of giving birth to those combinations-- 20 of imparting to them those modifications, which your organic structure rendered you competent to discover. 21 Such was, as has been shown, that all-powerful Jupiter, who in the theology of the ancients, 22 was originally destined to represent the etherial, subtile matter that penetrates, vivifies, and gives activity to all the bodies of which Nature is the common assemblage.

23 It would be grossly deceiving ourselves to believe that the idea of spirituality, such as the subtilty of dreaming metaphysicians present it in these days, 24 was that which offered itself to our forefathers in the early stages of the human mind. 25 This immateriality, which excludes all analogy with anything but itself-- which bears no resemblance to anything of which human is

capacitated to have a knowledge, 26 was, as we have already observed, the slow, the tardy fruit of your imagination, after you had quitted experience, and renounced your reason. 27 People reared in luxurious leisure, unceasingly meditating, without the assistance of those natural helps with which attentive observation would have furnished them, 28 by degrees arrived at the formation of this incomprehensible quality, which is so fugitive, 29 that although human has been compelled to reverence it, to accredit it against all the evidence of your senses, 30 they have never yet been enabled to give any other explanation of its nature, than by using a term to which it is impossible to attach any intelligible idea.

31 Seraphis said, with tears in his eyes, "that in making him adopt the opinion of spirituality, they had deprived him of his God." 32 Many fathers of the church have given a human form to the Divinity, and treated all those as heretics who made Him spiritual. 33 Thus by dint of reasoning, by force of subtilising, the word spirit no longer presents any one image upon which the mind can fix itself; 34 when they are desirous to speak of it, it becomes impossible to understand them, seeing that each visionary paints it after own manner; 35 and in the portrait each forms, consults only own temperament, follows nothing but own imagination, adopts nothing but own peculiar reveries; 36 the only point in which they are at all in unison, is in assigning to it inconceivable qualities, 37 which they naturally enough believe are best suited to the incomprehensible beings they have delineated: 38 from the incompatible heap of these qualities, generally resulted a whole, whose existence they thus rendered impossible.

39 In short, this word, which has occupied the research of so many learned and intelligent people; 40 which is considered of such importance to humankind, has been, in consequence of theological reveries, always fluctuating: 41 these never bearing the least resemblance to each other, it has become destitute

of any fixed sense, a mere sound, 42 to which each who echoes it affixes own peculiar ideas, which are never in harmony with those of own neighbour; 43 which indeed are not even steady in oneself, but like the camelion, assume the colour of every differing circumstance. 44 This unintelligible word has been substituted for the more intelligible one of matter; 45 human, when clothed with power, has entertained the most rancorous antipathies, pursued the most barbarous persecutions, 46 against those who have not been enabled to contemplate this changeable idea under the same point of view with the self.

47 There have, however, been people who had sufficient courage to resist this torrent of opinion-- to oppose themselves to this delirium; 48 who have believed, that the object which was announced as the most important for mortals, as the sole object worthy of their thoughts, demanded an attentive examination; 49 who apprehended that if experience could be of any utility, if judgment could afford any advantage, if reason was of any use whatever, 50 it must, most unquestionably be, to consider this quality so opposed to everything in Nature, which was said to regulate all the beings which She contains. 51 These quickly saw they could not subscribe to the general opinion of the uninformed, who never examine anything, who take everything upon the credit of others; 52 much less was it consistent with sound sense to agree with their guides, who, either deceivers or deceived, forbade others to submit it to the scrutiny of reason; 53 who were themselves frequently in an utter incapacity to pass it under such an ordeal.

54 Thus some thinkers, disgusted with the obscure and contradictory notions which others had through habit mechanically attached to this incomprehensible property, 55 had the temerity to shake off the yoke which had been imposed upon them from their infancy: 56 calling reason to their aid against those terrors with which they alarmed the ignorant, 57 revolting at the hideous descriptions

under which they attempted to defend their hypothesis, 58 they had the intrepidity to tear the veil of delusion; to rend asunder the barriers of imposture; 59 they considered with calm resolution, this formidable prejudice, contemplated with a serene eye this unsupported opinion, examined with cool deliberation this fluctuating notion, 60 which had become the object of all the hopes, the source of all the fears, the spring of all the quarrels which distracted the mind, and disturbed the harmony of blind, confiding mortals.

61 The result of these inquiries has uniformly been, a conviction that no rational proof has ever been adduced in support of this hypothesis; 62 that from the nature of the thing itself, none can be offered; 63 that an incorporeity is inconceivable to corporeal beings; that these only behold nature acting after invariable laws, in which everything is material; 64 that all the phenomena of which the world is the theatre, spring out of natural causes; 65 that human as well as all the other beings is the work of this Nature, and only an instrument in Her hand, obliged to accomplish the eternal decrees of an imperious necessity.

66 Whatever efforts the philosopher makes to penetrate the secrets of Nature, they never finds more, as we have many times repeated, than matter; 67 various in itself, diversely modified in consequence of the motion it undergoes. 68 Its whole, as well as its parts, displays only necessary causes producing necessary effects, which flow necessarily one out of the other: 69 of which the mind, aided by experience, is more or less competent to discover the concatenation. 70 In virtue of their specific properties, all the beings that come under our review, gravitate towards a centre-- 71 attract analogous matter-- repel that which is unsuitable to combination-- mutually receive and give impulse-- acquire qualities-- undergo modifications 72 which maintain them in existence for a season--are born and dissolved by the operation of an inexorable decree, that obliges everything, we behold to pass into a new mode of existence. 73 It is to

these continued vicissitudes that are to be ascribed all the phenomena, whether trivial or of magnitude; 74 ordinary or extraordinary; known or unknown; simple or complicated; which are operated in the universe. 75 It is by these mutations alone that we have any knowledge of Nature: 76 She is only mysterious to those who contemplate Her through the veil of prejudice: Her course is always simple to those who look at Her without prepossession.

77 To attribute the effects to which we are witnesses, to Nature, to matter, variously combined with the motion that is inherent to it, is to give them an intelligible and known cause; 78 to attempt to penetrate deeper, is to plunge ourselves into imaginary regions, where we find only a chaos of obscurities-- 79 where we are lost in an unfathomable abyss of incertitude. 80 Let us then be content with contemplating Nature, who, being self-existent, must in Her essence possess motion; 81 which cannot be conceived without properties, from which result perpetual action and re-action; 82 or those continual efforts which give birth to such a numerous train of circumstances; in which a single molecule cannot be found, 83 that does not necessarily occupy the place assigned to it, by immutable and necessary laws-- that is for an instant in an absolute state of repose. 84 What necessity can there exist to seek out of matter for a power to give it play, 85 since its motion flows as necessarily out of its existence as its bulk, its form, its gravity, since Nature in inaction would no longer be Nature?

86 If it be demanded: how can we figure to ourselves, that matter by its own peculiar energy can produce all the effects we witness? 87 I shall reply, that if by matter it is obstinately determined to understand nothing but a dead, inert mass, destitute of every property, incapable of moving itself, 88 we shall no longer have a single idea of matter; we shall no longer be able to account for anything. 89 As soon, however, as it exists, it must have properties; as soon as it has properties, without which it could not exist, it must act

by virtue of those properties; 90 since it is only by its action we can have a knowledge of its existence, be conscious of its properties. 91 It is evident that if by matter be understood that which it is not, or if its existence be denied, those phenomena which strike our visual organs cannot be attributed to it. 92 But if by Nature be understood-- that which She really is,-- an heap of existing matter, possessing various properties, 93 we shall be obliged to acknowledge that Nature must be competent to move Herself; 94 by the diversity of Her motion, must have the capability, independent of foreign aid, to produce the effects we behold; 95 we shall find that nothing can be made from nothing; that nothing is made by chance; 96 that the mode of action of every particle of matter, however minute, is necessarily determined by its own peculiar, or by its individual properties.

97 We have elsewhere said, that that which cannot be annihilated--that which in its nature is indestructible-- cannot have been inchoate, 98 cannot have had a beginning to its existence, but exists necessarily from all eternity; 99 contains within itself a sufficient cause for its own peculiar existence. 100 It becomes then perfectly useless to seek out of Nature a cause for Her action which is in some respects known to us; 101 with which indefatigable research may, judging of the future by the past, render us more familiar. 102 As we know some of the general properties of matter; as we can discover some of its qualities, 103 wherefore should we seek its motion in an unintelligible cause, of which we are not in a condition to become acquainted with any one of its properties? 104 Can we conceive that immateriality could ever draw matter from its own source? 105 Impossible; it is not within the grasp of human intellect.

106 If creation is an deduction from nothing, there must have been a time when matter had not existence; there must consequently be a time when it will cease to be: 107 this latter is acknowledged by many theologians themselves to be impossible. 108 Do

those who are continually talking of this mysterious act of omnipotence, by which a mass of matter has been, all at once, substituted to nothing, perfectly understand what they tell us? 109 Is there a person on earth who conceives that a being devoid of extent can exist, 110 become the cause of the existence of beings who have extent-- act upon matter-- draw it from his own peculiar essence-- set it in motion? 111 In truth, the more we consider theology, the more we must be convinced that it has invented words destitute of sense; substituted sounds to intelligible realities.

112 For want of consulting experience, for want of studying Nature, for want of examining the material world, we have plunged ourselves into an intellectual vacuum, 113 which we have peopled with chimeras, we have not stooped to consider matter, to study its different periods, to follow it through its numerous, changes. 114 We have either ridiculously or knavishly confounded dissolution, decomposition, the separation of the elementary particles of bodies, with their radical destruction; 115 we have been unwilling to see that the elements are indestructible; although the forms are fleeting, and depend upon transitory combination. 116 We have not distinguished the change of figure, the alteration of position, the mutation of texture, to which matter is liable, from its annihilation, which is impossible; 117 we have falsely concluded, that matter was not a necessary being-- that it commenced to exist-- 118 that this existence was derived from that which possessed nothing in common with itself-- that that which was not substance, could give birth to that which is. 119 Thus an unintelligible name has been substituted for matter, which furnishes us with true ideas of Nature; 120 of which at each instant we experience the influence, of which we undergo the action, of which we feel the power, 121 and of which we should have a much better knowledge, if our abstract opinions did not continually fasten a bandage over our eyes.

122 Indeed the most simple notions of philosophy show us, that, although bodies change and disappear, nothing is however lost in Nature; 123 the various produce of the decomposition of a body serves for elements, supplies materials, forms the basis, lays the foundation for accretions, contributes to the maintenance of other bodies. 124 The whole of Nature subsists, and is conserved only by the circulation, the transmigration, the exchange, the perpetual displacement of insensible atoms-- 125 the continual mutation of the sensible combinations of matter.

126 It is by this palingenesia, this regeneration, that the great whole, the mighty macrocosm subsists; 127 who, like the Saturn of the ancients, is perpetually occupied with devouring her own children.

128 It will not then be inconsistent with observation, repugnant to reason, contrary to good sense, to acknowledge that matter is self-existent; 129 that it acts by an energy peculiar to itself; that it will never be annihilated. 130 Let us then say, that matter is eternal; that Nature has been, is, and ever will be occupied with producing and destroying; with doing and undoing; with combining and separating; 131 in short, with following a system of laws resulting from its necessary existence. 132 For everything that She doth, She needs only to combine the elements of matter; 133 these, essentially diverse, necessarily either attract or repel each other; come into collision, from whence results either their union or dissolution; 134 by the same laws that one approximates, the other recedes from their respective spheres of action.

135 It is thus that She brings forth plants, fossils, animals, humans; 136 thus She gives existence to organised, sensible, thinking beings, as well as to those who are destitute of either feeling or thought. 137 All these act for the season of their respective duration, according to immutable laws, determined by their various properties; 138 arising out of their configuration; depending on their masses; resulting from their ponderousity, here is the true origin of everything which is presented to

our view; 139 this indicates the mode by which Nature, according to Her own peculiar powers, is in a state to produce all those astonishing effects which assail our wondering eyes; 140 all that phenomena to which humankind is the witness; as well as all the bodies who act diversely upon the organs with which you are furnished, 141 of which you can only judge according to the manner in which these organs are affected. 142 You says they are good, when they are analogous to your own mode of existence-- when they contribute to the maintenance of the harmony of your machine: 143 you says they are bad, when they disturb this harmony. 144 It is thus you ascribes views, ideas, designs, to the being you supposes to be the power by which Nature is moved; 145 although all the experience we are able to collect, unequivocally proves, that She acts after an invariable, eternal code of laws.

146 Nature is destitute of those views which actuate human; 147 She acts necessarily, because She exists: Her system is immutable, and founded upon the essence of things. 148 It is the essence of the seed of the male, composed of primitive elements, which serve for the basis of an organised being, to unite itself with that of the female; to fructify it; 149 to produce, by this combination, a new organised being; 150 who, feeble in own origin, not having yet acquired a sufficient quantity of material particles to give the self consistence, corroborates the self by degrees; 151 strengthens the self by the daily accretion of analogous matter; 152 is nourished by the modifications appropriate to own existence: matured by the continuation of circumstances calculated to give vigour to own frame; 153 thus you lives, thinks, acts, engenders in your turn other organised beings similar to yourself. 154 By a consequence of your temperament and of physical laws, this generation does not take place, 155 except when the circumstances necessary to its production find themselves united.

156 Thus this procreation is not operated by chance; the animal does

not fructify, but with an animal of own species, because this is the only one analogous to the self, 157 who unites the qualities, who combines the circumstances, suitable to produce a being resembling the self; 158 without this you would not produce anything, or you would only give birth to a being who would be denominated a monster, because it would be dissimilar to the self. 159 It is of the essence of the grain of plants, to be impregnated by the pollen or seed of the stigma of the flower; 160 in this state of copulation they in consequence develop themselves in the bowels of the earth; 161 expand by the aid of water; shoot forth by the accession of heat; attract analogous particles to corroborate their system: 162 thus by degrees they form a plant, a shrub, a tree, susceptible of that life, filled with that motion, capable of that action which is suitable to vegetable existence.

163 It is of the essence of particular particles of earth, homogeneous in their nature, when separated by circumstances, attenuated by water, elaborated by heat, 164 to unite themselves in the bosom of mountains, with other atoms which are analogous; 165 to form by their aggregation, according to their various affinities, those bodies possessing more or less solidity; 166 having more or less purity, which are called diamonds, chrystals, stones, metals, minerals. 167 It is of the essence of exhalations raised by the heat of the atmosphere, to combine, to collect themselves, to dash against each other, 168 and either by their union or their collision to produce meteors, to generate thunder.

169 It is of the essence of some inflammable matter to gather itself together, to ferment in the caverns of the earth, 170 to increase its active force by augmenting its heat, and then explode, by the accession of other matter suitable to the operation, 171 with that tremendous force which we call earthquakes; by which mountains are destroyed; cities overturned; the inhabitants of the plains thrown into a state of consternation; 172 these full of alarm, unused to meditate on natural effects,

unconscious of the extent of physical powers, stretch forth their hands in dismay, 173 heave the most desponding sighs, utter aloud their complaints, and earnestly implore a cessation of those evils, 174 which nature, acting by necessary laws, obliges them to experience as necessarily as She does those benefits by which She fills them with the most extravagant joy. 175 In short, it is of the essence of certain climates to produce humans so organised, whose temperament is so modified, 176 that they become either extremely useful or very prejudicial to their species, 177 in the same manner as it is the property of certain portions of the land, to bring forth either delicious fruits or dangerous poisons.

178 In all this Nature acts necessarily; She pursues an undeviating course, which we are bound to consider the perfection of wisdom; 179 because She exists necessarily, has Her modes of action determined by certain, invariable laws, 180 which themselves flow out of the constituent properties of the various beings She contains, and those circumstances, which the eternal motion She is in must necessarily bring about. 181 It is ourselves who have a necessary aim, which is our own conservation; 182 it is by this that we regulate all the ideas we form to ourselves of the causes acting in Nature; 183 it is according to this standard we judge of everything we see or feel. 184 Animated ourselves, existing after a certain manner, possessing a soul endowed with rare and peculiar qualities, 185 we, like the savage, ascribe a soul and animated life to everything that acts upon us. 186 Thinking and intelligent ourselves, we give these faculties to those beings whom we suppose to be more powerful than mortals; 187 but as we see the generality of matter incapable of modifying itself, we suppose it must receive its impulse from some concealed agent, 188 some external cause, which our imagination pictures as similar to ourselves.

189 Necessarily attracted by that which is advantageous to us, repelling by an equal necessity that

which is prejudicial to our manner of existence; 190 we cease to reflect that our modes of feeling are due to our peculiar organisation, modified by physical causes: 191 in this state, either of inattention or ignorance, we mistake the natural results of our own peculiar structure, 192 for instruments employed by a being whom we clothe with our own passions-- whom we suppose actuated by our own views-- 193 who, possessing our ideas, embraces a mode of thinking and acting similar to ourselves.

194 If after this it be asked, what is the end of Nature? 195 We shall reply that on this head we are ignorant; that it is more than probable no person will ever fathom the secret; 196 but we shall also say, it is evidently to exist, to act, to conserve Her whole. 197 If then it be demanded, wherefore She exists? We shall again reply, of this we know nothing at present, possibly never shall; 198 but we shall also say, She exists necessarily, that Her operations, Her motion, Her phenomena, are the necessary consequences of Her necessary existence.

200 There necessarily exists something; this is Nature or the universe, this Nature necessarily acts as She does. 201 If it be wished to substitute any other word for Nature, the question will still remain as it did, as to the cause of Her existence; the end She has in view. 202 It is not by changing of terms that a geometrician can solve problems; 203 one word will throw no more light on a subject than another, unless that word carries a certain degree of conviction in the ideas which it generates. 204 As long as we speak of matter, if we cannot develop all its properties, we shall at least have fixed, determinate ideas; 205 something tangible, of which we have a slight knowledge, that we can submit to the examination of our senses: 206 but from the moment we begin to talk of immateriality, of incorporeity, from thence our ideas become confused; 207 we are lost in a labyrinth of conjecture-- we have no one means of seizing the subject on any side-- 208 we are, after the most

elaborate arguments, after the most subtle reasoning, obliged to acknowledge we cannot form the most slender opinion respecting it, that has anything substantive for its support.

209 In short, that it is precisely that thing "of which everything may be denied, but of which nothing can with truth be affirmed." 210 Let us clothe this incomprehensible being with whatever qualities we may, it will be always in ourselves we seek the model; 211 they will be our own faculties that we delineate, our own passions that we describe. 212 In like manner human, as long as you are ignorant, will always conjecture that it is for yourself alone the universe was formed; 213 notwithstanding, you have nothing more to do, than to open your eyes in order to be undeceived. 214 You will then see, that you undergoes a common destiny, equally partakes with all other beings of the benefits, shares with them without exception the evils of life; 215 like them you are submitted to an imperious necessity, inexorable in its decrees; 216 which is itself nothing more than the sum total of those laws which Nature Herself is obliged to follow. 217 Thus everything proves that Nature, or matter, exists necessarily; 218 that it cannot in any moment swerve from those laws imposed upon it by its existence. 219 If it cannot be annihilated, it cannot have been inchoate.

220 The theologian themselves agrees that it requires a miracle to annihilate an atom. But is it possible to derogate from the necessary laws of existence? 221 Can that which exists necessarily, act but according to the laws peculiar to itself? 222 Miracle is another word invented to shield our own sloth, to cover our own ignorance; 223 it is that by which we wish to designate those rare occurrences, those solitary effects of natural causes, whose infrequency do not afford us means of diving into their springs. 224 It is only saying by another expression, that an unknown cause hath by modes which we cannot trace, 225 produced an uncommon effect which we did not expect, which therefore appears

strange to us. 226 This granted, the intervention of words, far from removing the ignorance in which we found ourselves 227 with respect to the power and capabilities of Nature, only serves to augment it, to give it more durability. 228 The creation of matter becomes to our mind as incomprehensible, and appears as impossible as its annihilation.

229 Let us then conclude that all those words which do not present to the mind any determinate idea, 230 ought to be banished the language of those who are desirous of speaking so as to be understood; 231 that abstract terms, invented by ignorance, are only calculated to satisfy people destitute of experience; 232 who are too slothful to study Nature, too timid to search into Her ways; 233 that they are suitable only to content those enthusiasts, whose curious imagination pleases itself with making fruitless endeavours to spring beyond the visible world; 234 who occupy themselves with chimeras of their own creation: 235 in short, that these words are useful only to those whose sole profession it is to feed the ears of the uninformed with pompous sounds, that are not comprehended by themselves-- 236 upon the sense of which they are in a state of perpetual hostility with each other-- 237 upon the true meaning of which they have never yet been able to come to a common agreement; 238 which each sees after own peculiar manner of contemplating objects, in which there never was, nor probably never will be, the least harmony of feeling.

239 Human is a material being; you cannot consequently have any ideas, but of that which like yourself is material; 240 that is to say, of that which is in a capacity to act upon your organs, which has some qualities analogous with your own. 241 In despite of yourself, you always assigns material properties to your gods; 242 the impossibility you finds in compassing them, has made you suppose them to be spiritual; distinguished from the material world. 243 Indeed you, must be content, either not to understand yourself, or you must have material

ideas of the Divinity; 244 the human mind may torture itself as long as it pleases, it will never, after all its efforts, be enabled to comprehend, that material effects can emanate from immaterial causes; 245 or that such causes can have any relation with material beings.

246 Here is the reason why human, as we have seen, believes the self obliged to give to own gods, 247 these morals which you so much so highly esteems, in those beings of your race, who are fortunate enough to possess them: 248 you forgets that a being who is spiritual, adopting the theological hypothesis, cannot from thence either have your organisation, or your ideas; 249 that it cannot think in own mode, nor act after your manner; 250 that consequently it cannot possess what you calls intelligence, wisdom, goodness, anger, justice, as you yourself understands those terms. 251 Thus, in truth, the moral qualities with which you has clothed the Divinity, supposes you material, 252 and the most abstract theological notions, are, after all, founded upon a direct, undeniable Anthropomorphism.

253 In despite of all their subtilties, the theologians cannot do otherwise; 254 like all the beings of the human species, they have a knowledge of matter alone: they have no real idea of a pure spirit. 255 When they speak of the intelligence, of the wisdom, of the designs of their gods, they are always those of people which they describe, 256 that they obstinately persist in giving to beings, of which, according to their own showing, to the evidence they themselves adduce, their essence does not render them susceptible; 257 who if they had those qualities with which they clothe them, would from that very moment cease to be incorporeal; 258 would be in the truest sense of the word, substantive matter.

259 How shall we reconcile the assertion, that beings who have not occasion for anything--who are sufficient to themselves-- 260 whose projects must be executed as soon as they are formed; can have volition, passions, desires? 261 How shall we attribute anger to beings without

either blood or bile? 262 How can we conceive an omnipotent being-- whose wisdom we admire in the striking order you have yourself established in the universe,-- 263 can permit that this beautiful arrangement should be continually disturbed, either by the elements in discord, or by the crimes of human beings? 264 In short, this being cannot have any one of the human qualities, which always depend upon the peculiar organisation of human-- 265 upon your wants-- upon your institutions, which are themselves always relative to the society in which you lives.

266 The theologian vainly strives to aggrandise, to exaggerate in idea, to carry to perfection by dint of abstraction, the moral qualities of human; they are unsuitable to the Divinity; 267 in vain it is asserted they are in Him of a different nature from what they are in His creatures; 268 that they are perfect; infinite; supreme; eminent; in holding this language, they no longer understand themselves; 269 they can have no one idea of the qualities they are describing, seeing that human can never have a conception of them, 270 but inasmuch as they bear an analogy to the same qualities in themselves.

271 It is thus that by force of metaphysical subtilty, mortals have no longer any fixed, any determinate ideas of the beings to which they have given birth. 272 But little contented with understanding physical causes, with contemplating active Nature; 273 weary of examining matter, which experience proves is competent to the production of everything, 274 human has been desirous to despoil it of the energy which it is its essence to possess, in order to invest it in a pure spirit; in an immaterial substance; 275 which you are under the necessity of re-making a material being, whenever you have an inclination either to form an idea of it to yourself, or make it understood by others.

276 In assembling the parts of human, which you does no more than enlarge, which you swells out to infinity, you believes you forms an immaterial being, 277 who, for that

reason, acquires the capability of performing all those phenomena, with the true causes of which you are ignorant; 278 nevertheless those operations of which you does comprehend the spring, you as sedulously denies to be due to the powers of this being; 279 time, therefore, according to these ideas, as you advances the progress of science, as you further develops the secrets of Nature, 280 is continually diminishing the number of actions ascribed to this being-- is constantly circumscribing human sphere of action.

281 It is upon the model of the human soul that you forms the soul of Nature, or that secret agent from which She receives impulse. 282 After having made yourself double, you makes Nature in like manner twofold, 283 and then you supposes She is vivified by an intelligence, which you borrows from yourself, 284 Placed in an impossibility of becoming acquainted with this agent, as well as with that which you have gratuitously distinguished from your own body; 285 you have invented the word spiritual to cover up your ignorance; which is only in other words avowing it is a substance entirely unknown to you. 286 From that moment, however, you have no ideas whatever of what you yourself has done; 287 because you first clothes it with all the qualities you esteems in your fellows, 288 and then destroys them by an assurance, that they in no wise resemble the qualities you have been so anxious to bestow. 289 To remedy this inconvenience, you concludes this spiritual substance much more noble than matter; 290 that its prodigious subtilty, which you calls simplicity, but which is only the effect of metaphysical abstraction, secures it from decomposition, from dissolution, 291 from all those revolutions, to which material bodies, as produced by Nature, are evidently exposed.

292 It is thus, that human always prefers the marvellous to the simple; the unintelligible to the intelligible; 293 that which you cannot comprehend, to that which is within the range of your understanding; 294

you despises those objects which are familiar to you; you estimates those alone with which you are incapable of having any intercourse: 295 that of which you have only confused vague ideas, you concludes must contain something important for you to know-- must have something supernatural in its construction. 296 In short, you needs mystery to move your imagination-- to exercise your mind-- to feed your curiosity; 297 which never labours harder, than when it is occupied with enigmas impossible to be guessed at; 298 which from that very circumstance, you judges to be extremely worthy of your research.

299 This, without doubt, is the reason you looks upon matter, which you have continually under your eyes, 300 which you sees perpetually in action, eternally changing its form, as a contemptible thing-- as a contingent being, that does not exist necessarily; 301 consequently, that cannot exist independently: this is the reason why you have imagined a spirit, which you will never be able to conceive; 302 which on that account you declares to be superior to matter; which you roundly asserts to be anterior to Nature, and the only self-existent being.

303 The human wind found food in these mystical ideas, they unceasingly occupied it; 304 the imagination had play, it embellished them after its own manner: 305 ignorance fed itself with the fables to which these mysteries gave rise; habit identified them with the existence of human: 306 when each could ask the other concerning these ideas, without any one being in a capacity to return a direct answer, you felt yourself gratified, 307 you immediately concluded that the general impossibility of reply stamped them with the wondrous faculty of immediately interesting your welfare; 308 of involving your most prominent interests, more than all the things put together, with which you had any possible means of becoming intimately acquainted. 309 Thus they became necessary to your happiness; you believed you fell into a vacuum without them; 310 you became the decided enemy to all

those who endeavoured to lead you back to Nature, which you had learned to despise; 311 to consider only as an impotent mass, an heap of inert matter, not possessing any energy but what it received from causes exterior to itself; 312 as a contemptible assemblage of fragile combinations, whose forms were continually subject to perish.

313 In distinguishing Nature from Her mover, human has fallen into the same absurdity as when you separated your soul from your body; 314 life from the living being; the faculty of thought from the thinking being: deceived on your own peculiar nature, 315 having taken up an erroneous opinion upon the energy of your own organs, you have in like manner been deceived upon the organisation of the universe; 316 you have distinguished Nature from Herself; the life of Nature from living Nature; the action of Nature from active Nature. 317 It was this soul of the world-- this energy of Nature-- this principle of activity, which human first personified, then separated by abstraction; 318 sometimes decorated with imaginary attributes; sometimes with qualities borrowed from your own peculiar essence. 319 Such were the aerial materials of which human availed the self to construct the incomprehensible, immaterial substances, which have filled the world with disputes-- 320 which have divided human from own fellow-- which to this day you have never been able to define, even to your own satisfaction. Your own soul was the model. 321 Deceived upon the nature of this, you never had any just ideas of the Divinity, 322 who was, in your mind, nothing more than a copy exaggerated or disfigured to that degree, as to make you mistake the prototype upon which it had been originally formed.

323 If, because human has distinguished the self from own existence, it has been impossible for you ever to form to yourself any true idea of your own nature; 324 it is also because you have distinguished Nature from Herself, that both Herself and Her ways have been mistaken. 325 Human has ceased to

study Nature, that you might, recur by thought to a substance which possesses nothing in common with Her; 326 this substance you have made the mover of Nature, without which She would not be capable of anything; 327 to whom everything that takes place in Her system, must be attributed; 328 the conduct of this being has appeared mysterious, has been held up as marvellous, because you seemed to be a continual contradiction: 329 when if human had but recurred to the immutability of the laws of Nature, to the invariable system She pursues, all would have appeared intelligible; 330 everything would have been reconciled; the apparent contrariety would have vanished.

331 By thus taking a wrong view of things, wisdom and intelligence appeared to be opposed by confusion and disorder; 332 goodness to be rendered nugatory by evil; while all is only just what it must inevitably be, under the given circumstances. 333 In consequence of these erroneous opinions, in the place of applying yourself to the study of Nature, to discover the method of obtaining Her favours, 334 or to seek the means of throwing aside your misfortunes; in the room of consulting your experience; in lieu of labouring usefully to your own happiness; 335 you have been only occupied with expecting these things by channels through which they do not flow; 336 you have been disputing upon objects you never can understand, while you have totally neglected that which was within the compass of your own powers; 337 which you might have rendered propitious to your views, by a more industrious application of your own talent; 338 by a patient investigation, for the purpose of drawing at the fountain of truth, the limpid balsam that alone can heal the sorrows of your heart.

339 Nothing could be well more prejudicial to the human race, than this extravagant theory; which, as we shall prove, has become the source of innumerable evils. 340 Human has been for thousands of years trembling before idols of own creation-- bowing down before them

with the most servile homage-- 341 occupied with disarming their wrath-- sedulously employed in propitiating their kindness, without ever advancing a single step on the road you so much desires to travel. 342 You will perhaps continue the same course for centuries to come, unless by some unlooked for exertion on your part, you shall happen to discard the prejudices which blind you; 343 to lay aside your enthusiasm for the marvellous; to quit your fondness for the enigmatical; rally round the standard of your reason: 344 unless, taking experience for your guide, you march undauntedly forward under the banner of truth, 345 and put to the rout that host of unintelligible jargon, under the cumbrous load of which you have lost sight of your own happiness; 346 which has but too frequently prevented you from seeking the only means adequate either to satisfy your wants, 347 or to ameliorate the evils which you are necessarily obliged to experience.

348 Let us then re-conduct bewildered mortals to the altar of Nature; 349 let us endeavour to destroy that delusion which the ignorance of human, aided by a disordered imagination, has induced you to elevate to Her throne; 350 let us strive to dissipate that heavy mist which obscures to you the paths of truth; 351 let us seek to banish from your mind those visionary ideas which prevent you from giving activity to your experience; 352 let us teach you if possible not to seek out of Nature Herself, the causes of the phenomena you admires--to rest satisfied that She contains remedies for all your evils-- 353 that She has manifold benefits in store for those, who, rallying their industry, are willingly patiently to investigate Her laws-- 354 that She rarely withholds Her secrets from the researches of those who diligently labour to unravel them.

355 Let us assure you that reason alone can render you happy; 356 that reason is nothing more than the science of Nature, applied to the conduct of human in society; 357 that this reason teaches that everything is necessary; 358 that your pleasures as

well as your sorrows are the effects of Nature, who in all Her works follows only laws which nothing can make Her revoke; 359 that your interest demands you should learn to support with equanimity of mind, all those evils which natural means do not enable you to put aside. 360 In short, let us unceasingly repeat to you, it is in rendering your fellow creature happy, that you will yourself arrive at a felicity you will in vain expect from others, when your own conduct refuses it to you.

361 Nature is self-existent; She will always exist; 362 She produces everything; contains within Herself the cause of everything; 363 Her motion is a necessary consequence of Her existence; without motion we could form no conception of Nature; 364 under this collective name we designate the assemblage of matter acting by virtue of its peculiar energies. 365 Everything proves to us, that it is not out of Nature human ought to seek the Divinity. 366 If we have only an incomplete knowledge of Nature and Her ways-- if we have only superficial, imperfect ideas of matter, 367 how shall we be able to flatter ourselves with understanding or having any certain notions of immateriality, 368 of beings so much more fugitive, so much more difficult to compass, even by thought, than the material elements; 369 so much more shy of access than either the constituent principles of bodies, their primitive properties, their various modes of acting, or their different manner of existing?

370 If we cannot recur to first causes, let its content ourselves with second causes, with those effects which we can submit to experience, 371 let us collect the facts with which we have an acquaintance; they will enable us to judge of what we do not know: 372 let us at least confine ourselves to the feeble glimmerings of truth with which our senses furnish us, 373 since we do not possess means whereby to acquire broader masses of light.

374 Do not let us mistake for real sciences, those which have no other basis than our imagination; we shall find that such can at most be but visionary: 375 let us cling close to

NATURE

Nature which we see, which we feel, of which we experience the action; of which at least we understand the general laws. 376 If we are ignorant of Her detail, if we cannot fathom the secret principles She employs in Her most complicated productions, 377 we are at least certain She acts in a permanent, uniform, analogous, necessary manner. 378 Let us then observe this Nature; let us watch Her movements; but never let us endeavour to quit the routine She prescribes for the beings of our species: 379 if we do, we shall not only be obliged to return, but we shall also infallibly be punished with numberless errors, which will darken our mind, estrange us from reason; 380 the necessary consequence will be countless sorrows, which we may otherwise avoid.

381 Let us consider we are sensible parts of a whole, in which the forms are only produced to be destroyed; 382 in which combinations are ushered into life, that they may again quit it, after having subsisted for a longer or a shorter season. 383 Let us look upon Nature as an immense elaboratory which contains everything necessary for Her action; 384 who lacks nothing requisite for the production of all the phenomena She displays to our sight. 385 Let us acknowledge Her power to be inherent in Her essence; amply commensurate to Her eternal march; fully adequate to the happiness of all the beings She contains. 386 Let us consider Her as a whole, who can only maintain Herself by what we call the discord of the elements; 387 that She exists by the continual dissolution and re-union of Her parts; 388 that from this springs the universal harmony; that from this the general stability has its birth. 389 Let us then re-establish omnipotent Nature, so long mistaken by human, in Her legitimate rights. 390 Let us place Her on that adamantine throne, which it is for the felicity of the human race She should occupy. 391 Let us surround Her with those ministers who can never deceive, who can never forfeit our confidence--Justice and Practical Knowledge. 392 Let us listen to Her eternal voice; She neither speaks

ambiguously, nor in an unintelligible language; 393 She may be easily comprehended by the people of all nations; because Reason is Her faithful interpreter. 394 She offers nothing to our contemplation but immutable truths.

395 Let us then forever impose silence on that enthusiasm which leads us astray; 396 let us put to the blush that imposture which would riot on our credulity; 397 let us discard that gloomy superstition, which has drawn us aside from the only worship suitable to intelligent beings. 398 Above all, never let us forget that the temple of happiness can only be reached through the groves of virtue, which surround it on every side; 399 that the paths which lead to these beautiful walks can only be entered by the road of experience, 400 the portals of which are alone opened to those who apply to them the key of truth: 401 this key is of very simple structure, has no complicated intricacy of wards, 402 and is easily formed on the anvil of social intercourse, merely by not doing unto others that which you would not wish they should do unto you.

OF THEISM.--OF THE SYSTEM OF OPTIMISM--OF FINAL CAUSES

Paul Henri Thiery (Baron D'Holbach)

50 Very few people have either the courage or the industry to examine opinions, which everyone is in agreement to acknowledge; 2 there is scarcely any one who ventures to doubt their truth, even when no solid arguments have been adduced in their support. 3 The natural supineness of human readily receives them without examination upon the authority of others-- 4 communicates them to own successors in the season of their infancy; 5 thus is transmitted from race to race, notions which once having obtained the sanction of time, are contemplated as clothed with a sacred character, 6 although perhaps to an unprejudiced mind, who should be bent on searching into their foundation, no proofs will appear, that they ever were verified. 7 It is thus with immateriality: it has

passed current from father to son for many ages, 8 without these having done anything more than habitually consign to their brain those obscure ideas which were at first attached to it, 9 which it is evident, from the admission even of its advocates, can never be removed, to admit others of a more enlightened nature.

10 Indeed how can it possibly be, that light can be thrown upon an incomprehensible subject: 11 each therefore modifies it after own manner; 12 each gives it that colouring that most harmonises with own peculiar existence; 13 each contemplates it under that perspective which is the issue of own particular vision: 14 this from the nature of things cannot be the same in every individual: 15 there must then of necessity be a great contrariety in the opinions resulting.

16 It is thus also that each person forms to the self a God in particular, after own peculiar temperament-- according to own natural dispositions: 17 the individual circumstances under which He is found, the warmth of your imagination, the prejudices you have received, 18 the mode in which you are at different times affected, have all their influence in the picture you forms. 19 The contented, healthy person, does not see Him with the same eyes as the person who is chagrined and sick; 20 the person with a heated blood, who has an ardent imagination, or is subject to bile, does not portray Him under the same traits 21 as one who enjoys a more peaceable soul, who has a cooler fancy, who is of a more phlegmatic habit. 22 This is not all; even the same individual does not view Him in the same manner at different periods of own life: 23 human undergoes all the variations of own machine-- all the revolutions of own temperament-- all those continual vicissitudes which your existence experiences.

24 The idea of the Divinity is said to be innate; on the contrary, it is perpetually fluctuating in the mind of each individual; 25 varies every moment in all the beings of the human species; so much so, that there are not two who admit

precisely the same Deity; 26 there is not a single one, who, under different circumstances, does not see Him variously. 27 Do not then let us be surprised at the variety of systems adopted by humankind on this subject; 28 it ought not to astonish us that there is so little harmony existing among humans upon a point of such consequence; 29 it ought not to appear strange that so much contradiction should prevail in the various doctrines held forth; 30 that they should have such little consistency, such slender connection with each other; 31 that the professors should dispute continually upon the rectitude of the opinions adopted by each: 32 they must necessarily wrangle upon that which each contemplates so variously--upon which there is hardly a single mortal who is constantly in accord with the self.

33 All people are pretty well agreed upon those objects which they are enabled to submit to the test of experience; 34 we do not hear any disputes upon the principles of geometry; those truths that are evident, that are easily demonstrable, never vary in our mind; 35 we never doubt that the part is less than the whole; that two and two make four; that benevolence is an amiable quality; that equity is necessary to human in society. 36 But we find nothing but perpetual controversy upon all those systems which have the Divinity for their object; 37 they are full of incertitude; subject to continual variations: we do not see any harmony either in the principles of theology, or in the principles of its graduates. 38 Even the proofs offered of His existence have been the subject of cavil; 39 they have either been thought too feeble, have been brought forward against rule, 40 or else have not been taken up with sufficient zeal to please the various reasoners who advocate the cause; 41 the corollaries drawn from the premises laid down, are not the same in any two nations, scarcely in two individuals; 42 the thinkers of all ages, in all countries, are perpetually in rivalry with each other; unceasingly quarrel upon all the points of religion; 43 can never agree

either upon their theological hypotheses, or upon the fundamental truths which should serve for their basis; 44 even the attributes, the very qualities ascribed, are as warmly contested by some, as they are zealously defended by others.

45 These never-ending disputes, these perpetual variations, ought, at least, to convince the unprejudiced, 46 that the ideas of the Divinity have neither the generally-admitted evidence, nor the certitude which are attributed to them; 47 on the contrary, these contrarieties in the opinions of the theologians, if submitted to the logic of the schools, might be fatal to the whole of them: 48 according to that mode of reasoning, which at least has the sanction of our universities, all the probabilities in the world cannot acquire the force of a demonstration; 49 a truth is not made evident but when constant experience, reiterated reflection, exhibits it always under the same point of view; 50 the evidence of a proposition cannot be admitted unless it carries with it a substantive demonstration; 51 from the constant relation which is made by well constituted senses, results that evidence, that certitude, which alone can produce full conviction: 52 if the major proposition of a syllogism should be overturned by the minor, the whole falls to the ground.

53 Cicero, who is no mean authority on such a subject, says expressly, "No reasoning can render that false, which experience has demonstrated as evident." 54 Wolff, in his Ontology, says; "That which is repugnant in itself, cannot possibly be understood; 55 that those things which are in themselves contradictions, must always be deficient of evidence." 56 St. Thomas says, "Being, is all that which is not repugnant to existence."

57 However it may be with these qualities, which the theologians assign to their immaterial beings, 58 whether they may be irreconcilable, or whether they are totally incomprehensible, what can result to the human species in supposing them to have intelligence and views? 59 Can an universal intelligence, whose care must be equally extended to

everything that exists, 60 have more direct, more intimate relations with human, who only forms an insensible portion of the great whole? 61 Can we seriously believe that it is to make joyful the insects, to gratify the ants of your garden, that the Monarch of the universe has constructed and embellished own habitation? 62 Would our feeble eyes, therefore, become stronger-- would our narrow views of things be enlarged-- 63 should we be better capacitated to understand His projects-- could we with more certitude divine His plans, enter into His designs-- 64 would our exility of judgment be competent to measure His wisdom, to follow the eternal order He has established?

65 Will those effects, which flow from His omnipotence, emanate from His providence-- 66 whether we estimate them as good, or whether we tax them as evil--whether we consider them beneficial, or view them as prejudicial-- 67 be less the necessary results of His wisdom, of His justice, of His eternal decrees? 68 In this case can we reasonably suppose that a Being, so wise, so just, so intelligent, will derange His system, change His plan, for such weak beings as ourselves? 69 Can we rationally believe we have the capacity to address worthy prayers, to make suitable requests, to point out proper modes of conduct to such a Being? 70 Can we at all flatter ourselves that to please us, to gratify our discordant wishes, He will alter His immutable laws? 71 Can we imagine that at our entreaty He will take from the beings who surround us their essences, their properties, their various modes of action? 72 Have we any right to expect He will abrogate in our behalf the eternal laws of Nature, 73 that He will disturb Her eternal march, arrest Her ever-lasting course, which His wisdom has planned; 74 which His goodness has conferred; which are, in fact, the admiration of humankind?

75 Can we hope that in our favour fire will cease to burn, when we approximate it too closely; 76 that fever shall not consume our habit, when contagion has penetrated our

system; 77 that gout shall not torment us, when an intemperate mode of life shall have amassed the humours that necessarily result from such conduct; 78 that an edifice tumbling in ruins shall not crush us by its fall, when we are within the vortex of its action? 79 Will our vain cries, our most fervent supplications, prevent a country from being unhappy, when it shall be devastated by an ambitious conqueror; 80 when it shall be submitted to the capricious will of unfeeling tyrants, who bend it beneath the iron rod of their oppression?

81 If this infinite intelligence gives a free course to those events which His wisdom has prepared; 82 if nothing happens in this world but after His impenetrable designs; 83 we ought silently to submit; we have in fact nothing to ask; we should be mad-people to oppose our own weak intellect to such capacious wisdom; 84 we should offer an insult to His prudence if we were desirous to regulate them. 85 Human must not flatter the self that you are wiser than your God; that you are in a capacity to make Him change His will; 86 with having power to determine Him to take other means than those which he has chosen to accomplish His decrees.

87 An intelligent Divinity can only have taken those measures which embrace complete justice; 88 can only have availed Himself of those means which are best calculated to arrive at His end; 89 if He was capable of changing them, He could neither be called wise, immutable, nor provident. 90 If it was to be granted, that the Divinity did for a single instant suspend those laws which He Himself has given, if He was to change anything in His plan, 91 it would be supposing He had not foreseen the motives of this suspension; that He had not calculated the causes of this change; 92 if He did not make these motives enter into His plan, it would be saying he had not foreseen the causes that render them necessary: 93 if He has foreseen them without making them part of His system, it would be arraigning the perfection of the whole.

94 Thus in whatever manner these things are contemplated, under whatever point of view they are examined, 95 it is evident that the prayers which human addresses to the Divinity, which are sanctioned by the different modes of worship, 96 always suppose He is supplicating a being whose wisdom and providence are defective; 97 in fact, that His own is more appropriate to His situation. 98 To suppose He is capable of change in His conduct, is to bring His omniscience into question; to vitally attack His omnipotence; to arraign His goodness; 99 at once to say, that He either is not willing or not competent to judge what would be most expedient for human; 100 for whose sole advantage and pleasure they will, notwithstanding, insist He created the universe: 101 such are the inconsistent doctrines of theology; such the imbecile efforts of metaphysics.

102 It is, however, upon these notions, extravagant as they may appear, ill directed as they assuredly are, inconclusive as they must be acknowledged by unprejudiced minds, 103 that are founded all the superstitions and many of the religions of the earth. 104 It is by no means an uncommon sight, to see human upon own knees before an all-wise God, whose conduct you are endeavouring to regulate; 105 whose decrees you wishes to avert; whose plan you are desirous to reform. 106 These inconsistent objects you are occupied with gaining, by means equally repugnant to sound sense; equally injurious to the dignity of the Divinity: 107 adopting your own sensations as the criterion of the feelings of the Deity; in some places you tries to win Him to your interests by presents; 108 sometimes we behold even the princes of the earth attempting to direct His views, by offering Him splendid garments, 109 upon which their own fatuity sets an inordinate value, merely because they have laboured at them themselves; 110 some strive to disarm His justice by the most splendid pageantry; others by practices the most revolting to humanity; 111 some think His immutability will yield to idle ceremonies; others to the most

discordant prayers; 112 it not infrequently happens that to induce Him to change in their favour His eternal decrees, those who have opposite interests to promote, 113 each returns Him thanks for that which the others consider as the greatest curse that can befall them.

114 In short, human is almost everywhere prostrate before an omnipotent God, 115 who, if we were to judge by the discrepancy of their requests, never has rendered His creatures such as they ought to be; 116 who to accomplish His divine views has never taken the proper measures, who to fulfil His wisdom has continual need of the admonitions of human, conveyed either in the form of thanks or prayers. 117 We see, then, that superstition is founded upon manifest contradictions, which human must always fall into when you mistakes the natural causes of things-- 118 when you shall attribute the good or evil which you experiences to an intelligent cause, distinguished from Nature, of which you will never be competent to form to yourself any certain ideas.

119 Indeed, human will always be reduced, as we have so frequently repeated, to the necessity of clothing your own gods with your own imbecile qualities: 120 as you are yourself a changeable being, whose intelligence is limited; 121 who, placed in divers circumstances, appears to be frequently in contradiction with yourself; 122 although you thinks you honours your gods in giving them your own peculiar qualities, 123 you in fact does nothing more than lend them your own inconstancy, cover them with your own weakness, invest them with your own vices. 124 It is thus that in reasoning, you are unable to account for the necessity of things-- 125 that you imagines there is a confusion which your prayers will have a tendency to remove-- 126 that you thinks the evils of life more than commensurate with the good: 127 you does not perceive that an undeviating system, by operating upon beings diversely organised, whose circumstances are different,

128 whose modes of action are at variance, must of necessity sometimes appear to be inimical to the interests of the individual, while it embraces the general good of the whole.

129 The theologian may subtilise, exaggerate, render as unintelligible as they pleases, the attributes with which they clothes their divinities, 130 they will never be able to remove the contradictions which arise from the discordant qualities which they thus heaps together; 131 neither will they be able to give human any other mode of judging than what arises from the exercise of their senses, such as they are actually found. 132 You will never be able to furnish the idea of an immutable being, while you shall represent this being as capable of being irritated and appeased by the prayers of mortals. 133 You will never delineate the features of omnipotence under the portrait of a being who cannot restrain the actions of own inferiors. 134 You will never hold up a standard of justice, while you shall mingle it with mercy, however amiable the quality; 135 or while you shall represent it as punishing those actions, which the perpetrators were under the necessity of committing. 136 Neither will you be able, under any circumstances, to make a finite mind comprehend infinity; much less when you shall represent this infinity as bounded by finity itself.

137 From this it will be obvious, that immaterial substances, such as are depicted by the theologians, can only be looked upon as the offspring of a metaphysical brain, 138 unsupported by any of those proofs which are usually required to establish the propositions laid down among humans; 139 all the qualities which they ascribe to them, are only those which are suitable to material substances; 140 all the abstract properties with which they invest them, are incomprehensible by material beings; 141 the whole taken together, is one confused mass of contradictions: 142 they have held forth to human, that it highly imported to your interests to know, to understand these substances; 143 you have consequently set your

intellect in action to discover some means of compassing an end, said to be so consequential to your welfare; 144 you have, however, been unable to make any progress, because no clue could be offered to you of the road you must pursue; 145 all was mere assertion unsupported by evidence; 146 the whole was enveloped in complete darkness, into which the least scintillation of light could never penetrate. 147 Notwithstanding, as soon as human believes the self greatly interested in knowing a thing, you labours to form to yourself an idea of that, the knowledge of which you thinks so important; 148 if insuperable obstacles impede your inquiries-- if difficulties of a magnitude to alarm your industry intervene--if with immense labour you makes but little progress, 149 then the slender success that attends your research, aided by a slothful disposition, while it wearies your diligence disposes you to credulity. 150 It was thus, that a crafty ambitious Arab, subtle and knavish in his manners, insinuating in his address, profiting by this credulous inclination, 151 made his countrymen adopt his own fanciful reveries as permanent truths, of which it was not permitted them for an instant to doubt; 152 following up these opinions with enthusiasm, he stimulated them on to become conquerors; 153 obliging the conquered to lend themselves to his system, he gave currency to a creed, invented solely for the purpose of enslaving humankind, 154 which now spreads over immense regions inhabited by a numerous population, 155 although like other systems it does not escape sectarianism, having above seventy branches.

156 Thus ignorance, despair, sloth, the want of reflecting habits, place the human race in a state of dependence upon those who build up systems, 157 while upon the objects which are the foundations, they have no one settled idea: 158 once adopted, however, whenever these systems are brought into question, human either reasons in a very strange manner, or else is the dupe of very deceitful arguments: 159 when they are agitated, and you finds it impossible

to understand what is said concerning them when your mind cannot embrace the ambiguity of these doctrines, 160 you imagines those who speak to you are better acquainted with the objects of their discourse than yourself; 161 these seizing the favourable opportunity, do not let it slip, they reiterate to you with Stentorian lungs, 162 "That the most certain way is to agree with what they tell you; to allow yourself to be guided by them;" 163 in short, they persuade you to shut your eyes, that you may with greater perspicuity distinguish the road you are to travel: 164 once arrived at this influence, they indelibly fix their lessons; irrevocably chain you to the oar; 165 by holding up to your view the punishments intended for you by these imaginary beings, in case you refuses to accredit, in the most liberal manner, their marvellous inventions; 166 this argument, although it only supposes the thing in question, serves to close your mouth-- to put an end to your research; 167 alarmed, confused, bewildered, you seems convinced by this victorious reasoning--attaches to it a sacredness that fills you with awe-- 168 blindly conceives that they have much clearer ideas of the subject than yourself-- fears to perceive the palpable contradictions of the doctrines announced to you, 169 until, perhaps, some being, more subtle than those who have enslaved you, by labouring the point incessantly, attacking you on the weak side of your interest, 170 arrives at throwing the absurdity of your system into light, and finally succeeds by inducing you to adopt that of another set of speculators. 171 The uninformed person generally believes your priests have more senses than yourself; you takes them for superior beings; for divine humans. 172 You only sees that which these priests inform you that you must contemplate; to everything else your eyes are completely hoodwinked; 173 thus the authority of the priests frequently decides, without appeal, that which is useful perhaps only to the priesthood.

174 When we shall be disposed to recur to the origin of things, we shall

ever find that it has been human's imagination, 175 guided by human ignorance, under the influence of fear, which gave birth to your gods; 176 that enthusiasm or imposture have generally either embellished or disfigured them; 177 that credulity readily adopted the fabulous accounts which interested duplicity promulgated respecting them; 178 that these dispositions, sanctioned by time, became habitual. 179 Tyrants finding their advantage in sustaining them, have usually established their power upon the blindness of humankind, 180 and the superstitious fears with which it is always accompanied. 181 Thus, under whatever point of view it is considered, it will always be found that error cannot be useful to the human species.

182 Nevertheless, the happy enthusiast, when your soul is sensible of its enjoyments, when your softened imagination has occasion to paint to itself a seducing object, 183 to which you can render thanks for the kindness you experiences, will ask, 184 "Wherefore deprive me of a being that I see under the character of a sovereign, filled with wisdom, abounding in goodness? 185 What comfort do I not find in figuring to myself a powerful, intelligent, indulgent monarch, of whom I am the favourite; 186 who continually occupies Himself with my welfare-- unceasingly watches over my safety--who perpetually administers to my wants--who always consents that under Him I shall command the whole of Nature? 187 I believe I behold Him constantly showering His benefits on human; I see His Providence labouring for my advantage without relaxation; 188 He covers the earth with verdure to delight me; He loads the trees with delicious fruits to gratify my palate; He fills the forests with animals suitable to my nourishment; 189 He suspends over His head planets with innumerable stars, to enlighten me by day, to guide my erring steps by night; 190 He extends around Him the azure firmament to gladden my sight; He decorates the meadows with flowers to please my fancy; 191 He causes crystal fountains to flow with

limpid streams to slake my thirst; 192 He makes rivulets meander through my lands to fructify the earth; He washes my residence with noble rivers, that yield my fish in abundance. 193 Ah! suffer me to thank thee, Author of so many benefits: do not deprive me of my charming sensations. 194 I shall not find my illusions so sweet, so consolatory in a severe destiny-- 195 in a rigid necessity-- in a blind inanimate matter-- in a nature destitute of intelligence, devoid of feeling."

196 "Wherefore," will say the unfortunate, from whom your destiny has rigorously withheld those benefits which have been lavished on so many others; 197 "wherefore ravish from me an error that is dear to me? 198 Wherefore annihilate to me a being, whose consoling idea dries up the source of my tears--who serves to calm my sorrows? 199 Wherefore deprive me of an object which I represent to myself as a compassionate, tender father; 200 who reproves me in this world, but into whose arms I throw myself with confidence, when the whole of Nature appears to have abandoned me? 201 Supposing it no more than a chimera, the unhappy have occasion for it, to guarantee them against frightful despair: 202 is it not cruel, is it not inhuman, to be desirous of plunging them into a vacuum, by seeking to undeceive them? 203 Is it not an useful error, preferable to those truths which deprive the mind of every consolation, which do not hold forth any relief from its sorrows?"

204 Thus will equally reason the Negro, the Mussulman, the Brachman, and others. We shall reply to these enthusiasts, No! truth can never render you unhappy; 205 it is this which really consoles us; it is a concealed treasure, much superior to all the superstitions ever invented by fear; 206 it can cheer the heart; give it courage to support the burthens of life; make us smile under adversity; 207 elevate the soul; render it active; furnishes it with means to resist the attacks of fate; to combat misfortunes with success. 208 This will show clearly that the good and

evil of life are distributed with an equal hand, without respect to human's peculiar comforts; 209 that all beings are equally regarded in the universe; that everything is submitted to necessary laws; 210 that human has no right whatever to think the self a being peculiarly favoured-- who is exempted from the common operations of the eternal routine; 211 that it is folly to think you are the only being considered-- one for whose enjoyment alone everything is produced; 212 an attention to facts will suffice to put an end to this delusion, however pleasant may be the indulgence of such a notion; 213 the most superficial glance of the eye will be sufficient to undeceive us in the idea, that you are the final cause of the creation-- 214 the constant object of the labours of Nature, or of its Author.

215 Let us seriously ask you, if you does not witness good constantly blended with evil? If you does not equally partake of them with the other beings in Nature? 216 To be obstinately bent to see only the evil, is as irrational as to be willing only to notice the good. 217 Providence seems to be just as much occupied for one class of beings as for another. 218 We see the calm succeed the storm; sickness give place to health; the blessings of peace follow the calamities of war; 219 the earth in every country bring forth roots necessary for the nourishment of human, produce others suitable to human destruction. 220 Each individual of the human species is a compound of good and bad qualities; 221 all nations present a varied spectacle of virtues, growing up beside vices; that which gladdens one being, plunges another into sadness-- 222 no event takes place that does not give birth to advantages for some, to disadvantages for others. 223 Insects find a safe retreat in the ruin of the palace, which crushes human in its fall; 224 human by your death furnishes food for myriads of contemptible insects; 225 animals are destroyed by thousands that you may increase your bulk; linger out for a season a feverish existence.

226 We see beings engaged in perpetual hostility, each living at

own neighbour's expense; the one banqueting upon that which causes the desolation of the other; 227 some luxuriously growing into flesh upon the misery which wears others into skeletons--profiting by misfortunes, rioting upon disasters, which ultimately, reciprocally destroy them. 228 The most deadly poisons spring up beside the most wholesome fruits 229 the earth equally nourishes the fatal steel which terminates human's career, and the fruitful corn that prolongs your existence; 230 the bane and its antidote are near neighbours, repose on the same bosom, ripen under the same sun, equally court the hand of the incautious stranger.

231 The rivers which human believes flow for no other purpose than to irrigate own residence, sometimes swell their waters, overtop their banks, inundate their fields, overturn their dwelling, and sweep away the flock and shepherd. 232 The ocean, which you vainly imagines was only collected together to facilitate your commerce supply you with fish, and wash your shores; 233 often wrecks your ships, frequently bursts its boundaries, lays waste your lands, destroys the produce of your industry, and commits the most frightful ravages. 234 The halcyon, delighted with the tempest, voluntarily mingles with the storm; rides contentedly upon the surge; 235 rejoiced by the fearful howlings of the northern blast, plays with happy buoyancy upon the foaming billows, that have ruthlessly dashed in pieces the vessel of the unfortunate mariner; 236 who, plunged into an abyss of misery, with tremulous emotion clings to the wreck; 237 views with horrific despair, the premature destruction of your indulged hopes; 238 sighs deeply at the thoughts of home; with aching heart, thinks of the cherished friends your streaming eyes will never more behold 239 in an agony of soul dwells upon the faithful affection of an adored wife, who will never again repose her drooping head upon a manly bosom; 240 grows wild with the appalling remembrance of beloved children, your wearied arms will never more encircle with parental fondness; 241

then sinks forever, the unhappy victim of circumstances that fill with glee the fluttering bird, who sees you yield to the overwhelming force of the infuriate waves. 242 The conqueror displays his military skill, fights a sanguinary battle, puts his enemy to the rout, lays waste his country, slaughters thousands of his fellows, 243 plunges whole districts into tears, fills the land with the moans of the fatherless, the wailings of the widow, 244 in order that the crows may have a banquet-- that ferocious beasts may gluttonously gorge themselves with human gore-- that worms may riot in luxury.

245 Thus when there is a question concerning an agent we see act so variously; whose motives seem sometimes to be advantageous, sometimes disadvantageous for the human race; 246 at least each individual will judge after the peculiar mode in which you are yourself affected; 247 there will consequently be no fixed point, no general standard in the opinions people will form to themselves. 248 Indeed our mode of judging will always be governed by our manner of seeing, by our way of feeling. 249 This will depend upon our temperament, which itself springs out of our organisation, and the peculiarity of the circumstances in which we are placed; 250 these can never be the same for all the beings of our species.

251 These individual modes of being affected, then, will always furnish the colours of the portrait which human may paint to the self of the Divinity; 252 it must therefore be obvious they can never be determinate-- can have no fixity-- can never be reduced to any graduated scale; 253 the inductions which they may draw from them, can never be either constant or uniform; 254 each will always judge after the self, will never see anything but the self or your own peculiar situation in the picture you delineates.

255 This granted, the person who has a contented, sensible soul, with a lively imagination, will paint the Divinity under the most charming traits; 256 you will believe that you sees in the whole of Nature nothing

but proofs of benevolence, evidence of goodness, because it will unceasingly cause you agreeable sensations. 257 In your poetical ecstasy you will imagine you everywhere perceives the impression of a perfect intelligence-- of an infinite wisdom-- of a providence tenderly occupied with the welfare of human; 258 self-love joining itself to these exalted qualities, will put the finishing hand to your persuasion, that the universe is made solely for the human race; 259 you will strive in imagination to kiss with transport the hand from which you believes you receives so many benefits; 260 touched with His kindness, gratified with the perfume of roses whose thorns you does not perceive, or which your ecstatic delirium prevents you from feeling, 261 you will think you can never sufficiently acknowledge the necessary effects, which you will look upon as indubitable testimony of the divine predilection for human.

262 Completely inebriated with these feelings, this enthusiast will not behold those sorrows, will not notice that confusion of which the universe is the theatre: 263 or if it so happens, you cannot prevent yourself from being a witness, you will be persuaded that in the views of an indulgent providence, 264 these calamities are necessary to conduct human to a higher state of felicity; 265 the reliance which you have in the Divinity, upon whom you imagines they depend, induces you to believe, that human only suffers for own good; 266 that this being, who is fruitful in resources, will know how to make you reap advantage from the evils which you experiences in this world: 267 your mind thus pre-occupied, from thence sees nothing that does not elicit your admiration call forth your gratitude; excite your confidence; 268 even those effects which are the most natural, the most necessary, appear in your eyes miracles of benevolence; prodigies of goodness: 269 you shuts your eyes to the disorders which could bring these amiable qualities into question: 270 the most cruel calamities, the most afflicting events, the most heart-rending

circumstances, cease to be disorders in your eyes, 271 and do nothing, more than furnish you with new proofs of the divine perfections; 272 you persuades yourself that what appears defective or imperfect, is only so in appearance; 273 you admires the wisdom, acknowledges the bounty of the Divinity, 274 even in those effects which are the most terrible for your race-- most suitable to discourage your species--most fraught with misery for your fellow.

275 It is, without doubt, to this happy disposition of the human mind, in some beings of your order, that is to be ascribed the system of Optimism, 276 by which enthusiasts, furnished with a romantic imagination, seem to have renounced the evidence of their senses: 277 to find that even for human everything is good in Nature, where the good has constantly its concomitant evil, 278 and where minds less prejudiced, less poetical, would judge that everything is only that which it can be-- 279 that the good and the evil are equally necessary-- that they have their source in the nature of things; 280 moreover, in order to attribute any particular character to the events that take place, it would be needful to know the aim of the whole: 281 now the whole cannot have an aim, because if it had a tendency, an aim, or end, it would no longer be the whole, seeing that that to which it tended would be a part not included.

282 It will be asserted by some, that the evils which we behold in this world are only relative, merely apparent; that they prove nothing against the good: 283 but does not human almost uniformly judge after own mode of feeling; after own manner of co-existing with those causes by which you are encompassed; 284 which constitute the order of Nature with relation to the self; 285 consequently, you ascribes wisdom and goodness to all that which affects you pleasantly, disorder to that state of things by which you are injured. 286 Nevertheless everything which we witness in the world conspires to prove to us, that whatever is, is necessary; that nothing is done by chance; 287 that all the events, good

or bad, whether for us or for beings of a different order, are brought about by causes acting after certain and determinate laws; 288 that nothing can be a sufficient warranty in us to clothe with any one of our human qualities, either Nature or the motive-power which has been given to Her.

289 With respect to those who pretend that supreme wisdom will know how to draw the greatest benefits for us, 290 even out of the bosom of those calamities which it is permitted we shall experience in this world; 291 we shall ask them, if they are themselves the confidents of the Divinity; or upon what they found these assertions so flattering to their hopes? 292 They will, without doubt, tell us they judge by analogy; that from the actual proofs of goodness and wisdom, they have a just right to conclude in favour of future bounty. 293 Would it not be a fair reply to ask, if they reason by analogy, and human has not been rendered completely happy in this world, what analogy informs them human will be so in another? 294 If, according to their own showing, human is sometimes made the victim of evil in own present existence, in order that you may attain a greater good, 295 does not analogical reasoning, which they say they adopt, clearly warrant a deduction, 296 that the same afflictions, for the same purposes, will be equally proper, equally requisite in the world to come?

297 Thus this language founds itself upon ruinous hypotheses, which have for their bases only a prejudiced imagination. 298 It, in fact, signifies nothing more than that human once persuaded, without any evidence, of own future happiness, will not believe it possible you can be permitted to be unhappy: 299 but might it not be inquired what testimony does you find, what substantive knowledge has you obtained of the peculiar good that results to the human species from those sterilities, 300 from those famines, from those contagions, from those sanguinary conflicts, which cause so many millions of people to perish; 301 which unceasingly depopulate the earth, and desolate

the world we inhabit? 302 Is there anyone who has sufficient compass of comprehension to ascertain the advantages that result from the evils that besiege us on all sides? 303 Do we not daily witness beings consecrated to misfortune, from the moment they quitted the womb of the parent who brought them into existence, 304 until that which re-committed them to the earth, to sleep in peace with their fathers; 305 who with great difficulty found time to respire; lived the constant sport of fortune; overwhelmed with affliction, immersed in grief, enduring the most cruel reverses? 306 Who is to measure the precise quantity of misery required to derive a certain portion of good? 307 Who is to say when the measure of evil will be full which it is necessary to suffer?

308 The most enthusiastic Optimists, the Theists themselves, the partisans of Natural-Religion, as well as the most credulous and superstitious, are obliged to recur to the system of another life, 309 to remedy the evils human is decreed to suffer in the present; 310 but have they really any just foundation to suppose the next world will afford you a happiness denied you in this? 311 If it is necessary to recur to a doctrine so little probable as that of a future existence, by what chain of reasoning do they establish their opinion, 312 that when you shall no longer have organs, by the aid of which you are at present alone enabled either to enjoy or to suffer, you shall be able to compensate the evils you has endured; 313 to enjoy a felicity, to partake of a pleasure this organic structure has refused you while on your pilgrimage through the land of your fathers and mothers.

314 From this it will be seen, that the proofs of a sovereign intelligence, or of a magnified human quality drawn from the order, from the harmony, from the beauty of the universe, 315 are never more than those which are derived from people who are organised and modified after a certain mode; 316 or whose cheerful imagination is so constructed as to give birth to agreeable chimeras which they embellish according to

their fancy: 317 these illusions, however, must be frequently dissipated even in themselves, whenever their machine becomes deranged; 318 when sorrows assail them, when misfortune corrodes their mind; 319 the spectacle of Nature, which under certain circumstances has appeared to them so delightful, so seducing, must then give place to disorder, must yield to confusion.

320 A person of melancholy temperament, soured by misfortunes, made irritable by infirmities, cannot view Nature and Her author under the same perspective, 321 as the healthy person of a sprightly humour, who is contented with everything. 322 Deprived of happiness, the fretful person can only find disorder, can see nothing but deformity, can find nothing but subjects to afflict the self with; 323 you only contemplates the universe as the theatre of malice, as the stage for tyrants to execute their vengeance; 324 you grows superstitious, you gives way to credulity, and not infrequently becomes cruel, in order to serve a master whom you believes you have offended.

325 In consequence of these ideas, which have their growth in an unhappy temperament, which originate in a peevish humour, which are the offspring of a disturbed imagination, 326 the superstitious are constantly infected with terror, are the slaves to mistrust, the creatures of discontent, continually in a state of fearful alarm. 327 Nature cannot have charms for them; Her countless beauties pass by unheeded; they do not participate in Her cheerful scenes; 328 they look upon this world, so marvellous to the happy human, so good to the contented enthusiast, as a valley of tears, 329 in which a vindictive fate has placed them only to expiate crimes committed either by themselves or by their fathers; 330 they consider themselves as sent here for no other purpose than to be the sharers of calamity; the sport of a capricious fortune; 331 that they are the children of sorrow, destined to undergo the severest trials, to the end that they

may everlastingly arrive at a new existence, 332 in which they shall be either happy or miserable, according to their conduct towards the ministers of a being who holds their destiny in own hands.

333 These dismal notions have been the source of all the irrational systems that have ever prevailed; 334 they have given birth to the most revolting practices, currency to the most absurd customs. 335 History abounds with details of the most atrocious cruelties, under the imposing name of public worship; 336 nothing has been considered either too fantastical or too flagitious by the votaries of superstition. 337 Parents have immolated their children; lovers have sacrificed the objects of their affection; friends have destroyed each other: 338 the most bloody disputes have been fomented; the most interminable animosities have been engendered, 339 to gratify the whim of implacable priests, who by crafty inventions have obtained an influence over the people; 340 to please blind zealots, who have never been able either to give fixity to their ideas, or to define their own feelings. 341 Idle dreamers nourished with bile, intoxicated with theologic fury--atrabilarians, whose melancholic humour frequently disposes them to wickedness-- 342 visionaries, whose devious imaginations, heated with intemperate zeal, generally leads them to the extremes of fanaticism, 343 working upon ignorance, whose usual bias is credulity, have incessantly disturbed the harmony of humankind, kindled the inextinguishable flame of discord, 344 and in an almost uninterrupted succession, strewed the earth with the mangled carcasses of the multitudinous victims to mad-brained error, 345 whose only crime has been their incapacity to dream according to the rules prescribed by these infuriate maniacs; 346 although these have never been uniform--never assimilated in any two countries-- 347 never borne the same features in any two ages, nor even had the united concurrence of the persecuting contemporaries.

NATURE

348 It is then in the diversity of temperament, arising from variety of organisation-- 349 in the contrariety of passions, springing out of this miscellany, modified by the most opposite circumstances, 350 that must be sought the difference we find in the opinions of the theist, the optimist, the happy enthusiast, the zealot, the devotee, the superstitious of all denominations; 351 they are all equally irrational-- the dupes of their imagination-- the blind children of error. 352 What one contemplates under a favourable point of view, the other never looks upon but on the dark side; 353 that which is the object of the most sedulous research to one set, is that which the others most seek to avoid: 354 each insists one is right; no one offers the least shadow of substantive proof of what they asserts; 355 each points out the great importance of own mission, yet cannot even agree with own colleagues in the embassy, either upon the nature of their instructions, or the means to be adopted.

356 It is thus whenever human sets forth a false supposition, all the reasonings you makes on it are only a long tissue of errors, which entail on you an endless series of misfortunes; 357 every time you renounces the evidence of your senses, it is impossible to calculate the bounds at which your imagination will stop; 358 when you once quits the road of experience, when you travels out of Nature, when you loses sight of your reason, to strike into the labyrinths of conjecture, 359 it is difficult to ascertain where your folly will lead you-- into what mischievous swamps this ‘ignis fatuus’ of the mind may beguile your wandering steps. 360 It is certainly true, the ideas of the happy enthusiast will be less dangerous to the self, less baneful to others, 361 than those of the atrabilarious fanatic, whose temperament may render you both cowardly and cruel; 362 nevertheless the opinions of the one and of the other will not be less chimerical; the only difference will be, that of the first will produce agreeable, cheerful dreams; 363 while that of the second will present the most appalling

visions, terrific spectres, the fruit of a peevish transport of the brain: 364 there will, however, never be more than a step between them all; 365 the smallest revolution in the machine, a slight infirmity, an unforeseen affliction, suffices to change the course of the humours-- 366 to vitiate the temperament-- to endanger the organisation-- to overturn the whole system of opinions of the happiest. 367 As soon as the portrait is found disfigured, the beautiful order of things is overthrown relatively to the self; 368 melancholy grapples you-- pusillanimity benumbs your faculties-- by degrees plunges you into the rankest depths of gloomy superstition; 369 you then degenerates into all those irregularities which are the dismal harvest of fanatic ignorance ploughed with credulity.

370 Those ideas, which have no archetype but in the imagination of human, must necessarily take their complexion from your own character; 371 must be clothed with your own passions; must constantly follow the revolutions of your machine; 372 be lively or gloomy; favourable or prejudicial; friendly or inimical; sociable or savage; humane or cruel; according as you whose brain they inhabit shall yourself be disposed; 373 in fact, they can never be more than the shadow of the substance you yourself interposes between the light and the ground on which they are thrown. 374 A mortal plunged from a state of happiness into misery, whose health merges into sickness, whose joy is changed into affliction, cannot in these vicissitudes preserve the same ideas; 375 these naturally depend every instant upon the variations, which physical sensations oblige your organs to undergo. 376 It will not therefore appear strange that these opinions should be fluctuating, when they depend upon the state of the nervous fluid, 377 upon the greater or less portion of igneous matter floating in the sanguinary vessels.

378 Theism, or what is called Natural Religion, cannot have certain principles; 379 those who profess it must necessarily be subject to vary in their opinions-- to fluctuate in their

conduct, which flows out of them. 380 A system founded upon wisdom and intelligence, which can never contradict itself, when circumstances change will presently be converted into fanaticism; rapidly degenerate into superstition; 381 such a system, successively meditated by enthusiasts of very distinct characters, must of necessity experience vicissitudes, and quickly depart from its primitive simplicity. 382 The greater part of those philosophers who have been disposed to substitute theism for superstition, have not felt that it was formed to corrupt itself-- to degenerate. 383 Striking examples, however, prove this fatal truth. Theism is almost everywhere corrupted; 384 it has by degrees given way to those superstitions, to those extravagant sects, to those prejudicial opinions with which the human species is degraded. 385 As soon as human consents to acknowledge invisible powers out of Nature, upon which your restless mind will never be able invariably to fix your ideas-- 386 which your imagination alone will be capable of painting to you; 387 whenever you shall not dare to consult your reason relatively to those powers, it must necessarily be, that the first false step leads you astray, 388 that your conduct as well as your opinions becomes in the long run perfectly absurd.

389 Those are usually called Theists, who, undeceived upon the greater number of grosser errors to which the uninformed, the superstitiously ignorant, tend the most determined support, 390 simply hold the notion of unknown agents endowed with intelligence, wisdom, power and goodness, 391 in short, full of infinite perfections, whom they distinguish from Nature, but whom they clothe after their own fashion; 392 to whom they ascribe their own limited views; whom they make act according to their own absurd passions. 393 The religion of Abraham appears to have originally been a kind of theism, imagined to reform the superstition of the Chaldeans; 394 Moses modified it, and gave it the Judaical form. 395 Socrates was a theist, who lost his life in his attack on

polytheism; 396 his disciple Aristotle, or Plato, as he was afterwards called from his large followers, embellished the theism of his master, 397 with the mystical colours which he borrowed from the Egyptian and Chaldean priests, which he modified in his own poetical brain, and preserved a remnant of polytheism. 398 The disciples of Plato, such as Proclus, Ammonius, Jamblicus. Plotinus, Longinus, Porphyrus, and others, dressed it up still more fantastically, 399 added a great deal of superstitious mummery, blended it with magic, and other unintelligible doctrines.

400 The first doctors of Christianity were Platonists, who combined the reformed Judaism with the philosophy taught in Academia. 401 Mahomet, in combating the polytheism of his country, seems to have been desirous of restoring the primitive theism of Abraham, and his son Ishmael. 402 Thus it will be obvious, that theism has no fixed point, no standard, no common measure more than other systems: 403 that it runs from one supposition to another, to find in what manner evil has crept into the world. 404 Indeed it has been for this purpose, which perhaps after all will never be satisfactorily explained, that the doctrine of free-agency was introduced; 405 that the fable of Prometheus and the box of Pandora was imagined; that the history of the Titanes was invented; 406 notwithstanding, it must be evident that these things as well as all the other trappings of superstition, are not more difficult of comprehension than the immaterial substances of the theists; 407 the mind who can admit that beings devoid of parts, destitute of organs, without bulk, can move matter, think like human, have the moral qualities of human nature, 408 need not hesitate to allow that ceremonies, certain motions of the body, words, rites, temples, statues, can equally contain secret virtues; 409 has no occasion to withhold its faith from the concealed powers of magic, theurgy, enchantments, charms, talismans; 410 can show no good reason why it should not accredit inspirations, dreams,

visions, omens, soothsayers, metamorphoses, and all the host of occult sciences: 411 when things so contradictory to the dictates of reason, so completely opposed to good sense are freely admitted, 412 there can no longer be a thing which ought to possess the right to make credulity revolt; 413 those who give sanction to the one, may without much hesitation believe whatever else is offered to their credence.

414 It would be impossible to mark the precise point at which imagination ought to arrest itself-- 415 the exact boundary that should circumscribe belief-- the true dose of folly that may be permitted them; 416 or the degree of indulgence that can with safety be extended to those priests who are in the habit of teaching so variously, so contradictorily, 417 what human ought to think on the subjects they handle so advantageously to themselves; 418 who when it becomes a question what remuneration is due from humankind for their unwearied exertions in their favour, 419 are, in spite of all their other differences, in the most perfect union; 420 except perhaps when they come to the division of the spoil: in this, indeed, the apple of discord sometimes takes a tremendous roll.

421 Thus it will be clear that there can be no substantive grounds for separating the theists from the most superstitious; 422 that it becomes impossible to fix the line of demarcation, which divides them from the most credulous of people; 423 to show the land-marks by which they can be discriminated from those who reason with the least conclusive persuasion. 424 If the theist refuses to follow up the fanatic in every step of own gullibility, you are at least more inconsequent than the last, 425 who having admitted upon hearsay an inconsistent, whimsical doctrine, also adopts upon report the ridiculous, strange means which it furnishes you.

426 The first sets forth with an absurd supposition, of which you rejects the necessary consequences; the other admits both the principle and the conclusion. 427 There are no degrees in fiction any more than in truth. 428

If we admit the superstition, we are bound to receive everything which its ministers promulgate, as emanating from its principle. 429 None of the reveries of superstition embrace anything more incredible than immateriality; 430 these reveries are only corollaries drawn with more or less subtilty from unintelligible subjects, by those who have an interest in supporting the system. 431 The inductions which dreamers have made, by dint of meditating on impenetrable materials, are nothing more than ingenious conclusions, 432 which have been drawn with wonderful accuracy, from unknown premises, 433 that are modestly offered to the sanction of humankind by enthusiasts, who claim an unconditional assent, 434 because they assure us no one of the human race is in a capacity either to see, feel, or comprehend the object of their contemplation. 435 Does not this somewhat remind us of what Rabelais describes as the employment of Queen Whim's officers, in his fifth book and twenty-second chapter?

436 Let us then acknowledge, that the person who is this most credulously superstitious, reasons in a more conclusive manner, 437 or is at least more consistent in own credulity, than those, who, after having admitted a certain position of which they have no one idea, stop short all at once, 438 and refuse to accredit that system of conduct which is the immediate, the necessary result of a radical and primitive error. 439 As soon as they subscribe to a principle fatally opposed to reason, by what right do they dispute its consequences, however absurd they may be found?

440 We cannot too often repeat, for the happiness of humankind, that the human mind, let it torture itself as much as it will, when it quits visible Nature leads itself astray; 441 for want of an intelligent guide it wanders in tracks that bewilder its powers, and is quickly obliged, to return into that with which it has at least some, acquaintance. 442 If human mistakes Nature and Her energies, it is because you do not sufficiently study Her-- 443 because

you does not submit to the test of experience the phenomena you beholds; 444 if you will obstinately deprive Her of motion, you can no longer have any ideas of Her.

445 Does, you, however, elucidate your embarrassments, by submitting Her action to the agency of a being of which you makes yourself the model? 446 Does you think you forms a god, when you assembles into one heterogeneous mass, your own discrepant qualities, 447 magnified until your optics are no longer competent to recognise them, 448 and then unites to them certain abstract properties of which you cannot form to yourself any one conception? 449 Does you, in fact, do more than collect together that which becomes, in consequence of its association, perfectly unintelligible?

450 Yet, strange as it may appear, when you no longer understands yourself-- 451 when your mind, lost in its own fictions, becomes inadequate to decipher the characters you have thus promiscuously assembled-- 452 when you have huddled together a heap of incomprehensible, abstract qualities, which you are obliged to acknowledge are the mere creatures of imagination, not within the reach of human intellect, 453 you firmly persuades yourself you have made a most accurate and beautiful portrait of the Divinity; 454 you ostentatiously displays your picture, demands the eulogy of the spectator, 455 and quarrels with all those who do not agree to adulate your creative powers, by adopting the inconceivable being you holds forth to their worship; 456 in short, to question the existence of your extravaganza, rouses His most bitter reproaches; elicits His everlasting scorn; entails on the incredulous His eternal hatred.

457 On the other hand, what could we expect from such a being, as they have supposed Him to be? What could we consistently ask of Him? 458 How make an immaterial being, who has neither organs, space, point, or contact, understand that modification of matter called voice? 459 Admit that this is the being who moves Nature-- who establishes Her

laws--who gives to beings their various essences-- who endows them with their respective properties; 460 if everything that takes place is the fruit of His infinite providence-- the proof of His profound wisdom, to what end shall we address our prayers to Him? 461 Shall we solicit Him to acknowledge that the wisdom and providence with which we have clothed Him, are in fact erroneous, by entreating Him to alter in our favour His eternal laws?

462 Shall we give Him to understand our wisdom exceeds His own, by asking Him for our pleasure to change the properties of bodies-- 463 to annihilate His immutable decrees-- to trace back the invariable course of things-- to make beings act in opposition to the essences with which you have thought it right to invest them? 464 Will He at our intercession prevent a body ponderous and hard by its nature, such as a stone, for example, from wounding, in its fall a sensitive being such as the human frame? 465 Again, should we not, in fact, challenge impossibilities, if the discordant attributes brought into union by the theologians were correct; 466 would not immutability oppose itself to omnipotence; mercy to the exercise of rigid justice; omniscience, to the changes that might be required in foreseen plans?

467 In physics, in consequence of the general research after a perpetual motion, science has drawn forth the discovery, 468 that by amalgamating metals of contrary properties, the contractile powers of one kind, under given circumstances which cause the dilation of the other, 469 by their opposite tendencies neutralise the actual effects of each, taken separately, 470 and thus produce an equality in the oscillations, that, neither possessed individually. 471 It will perhaps, be insisted, that the infinite science of the Creator of all things, is acquainted with resources in the beings you have formed, which are concealed from imbecile mortals; 472 that consequently without changing anything, either in the laws of Nature, or in the essence of things, He is competent to produce effects which surpass the

comprehension of our feeble understanding; 473 that these effects will in no wise be contrary to that order which He Himself has established in Nature.

474 Granted: but then I reply, first, that everything which is conformable to the nature of things, can neither be called supernatural nor miraculous: 475 many things are, unquestionably, above our comprehension; 476 but then all that is operated in the world is natural--grows out of those immutable laws by which Nature is regulated. 477 In the second place, it will be requisite to observe, that by the word miracle an effect is designed, of which, for want of understanding Nature, She is believed incapable. 478 In the third place, it is worthy of remark, that the theologians, almost universally, insist that by miracle is meant not an extraordinary effort of Nature, 479 but an effect directly opposite to Her laws, which nevertheless they equally challenge to have been prescribed by the Divinity.

480 Buddaeus says, "a miracle is an operation by which the laws of Nature, upon which depend the order and the preservation of the universe, are suspended." 481 If, however, the Deity, in those phenomena that most excite our surprise, does nothing more than give play to springs unknown to mortals, 482 there is, then, nothing in Nature, which, in this sense, may not be looked upon as a miracle; 483 because the cause by which a stone falls is as unknown to us, as that which makes our globe turn on its own axis. 484 Thus, to explain the phenomena of Nature by a miracle, is, in other words, to say we are ignorant of the actuating causes; 485 to attribute them to the Divinity, is to agree we do not comprehend the resources of Nature: it is little better than accrediting magic. 486 To attribute to a sovereignty intelligent, immutable, provident, wise being, those miracles by which you derogates from your own laws, is at one blow to annihilate all these qualities: 487 it is an inconsistency that would shame a child.

488 It cannot be supposed that omnipotence has need of miracles to

govern the universe, 489 nor to convince His creatures, whose minds and hearts must be in His own hands. 490 The last refuge of the theologian, when driven off all other ground, is the possibility of everything they asserts, 491 couched in the dogma, "that nothing is impossible to the Divinity." 492 They makes this asseveration with a degree of self-complacency, with an air of triumph, that would almost persuade one they could not be mistaken; 493 most assuredly, with those who dip no further than the surface, they carries complete conviction. 494 But we must take leave to examine a little the nature of this proposition, 495 and we do apprehend that a very slight degree of consideration will show that it is untenable.

496 In the first place, as we have before observed, the possibility of a thing by no means proves its absolute existence: 497 a thing may be extremely possible, and yet not be. 498 Secondly, if this was once to become an admitted argument, there would be, in fact, an end of all morality and religion. 499 The Bishop of Chester, Doctor John Wilkins, says, "would not such people be generally accounted out of their wits, who could please themselves by entertaining actual hopes of anything, 500 merely upon account of the possibility of it, or torment themselves with actual fears of all such evils as are possible? 501 Is there anything imaginable more wild and extravagant amongst those in bedlam than this would be?" 502 Thirdly, the impossibility would reasonably appear to be on the other side, so far from nothing being impossible, everything that is erroneous would seem to be actually so; 503 the Divinity could not possibly either love vice, cherish crime, be pleased with depravity, or commit wrong; this decidedly turns the argument against them; 504 they must either admit the most monstrous of all suppositions, or retire from behind the shield with which they have imagined they rendered themselves invulnerable.

505 To those who may be inclined to inquire, whether it would not be better that all things were operated

by a good, wise, intelligent Being, than by a blind Nature, 506 in which not one consoling quality is found; by a fatal necessity always inexorable to human in treaty? 507 It may be replied, first, that our interest does not decide the reality of things, 508 and that when this should be even more advantageous than it is pointed out, it would prove nothing. 509 Secondly, that as we are obliged to admit some things are operated by Nature, it is certainly on the side of probability that She performs the others; 510 especially as Her capabilities are more substantively proved by every age as it advances. 511 Thirdly, that Nature duly studied furnishes everything necessary to render us as happy as our essence admits.

512 When, guided by experience, we shall consult Her, with cultivated reason; 513 She will discover to us our duties, that is to say, the indispensable means to which Her eternal and necessary laws have attached our preservation, our own happiness, and that of society. 514 It is decidedly in Her bosom that we shall find wherewith to satisfy our physical wants; 515 whatever is out of Nature, can have no existence relatively to ourselves. 516 Nature, then, is not a step-mother to us; we do not depend upon an inexorable destiny. 517 Let us therefore endeavour to become more familiar with Her resources; 518 She will procure us a multitude of benefits when we shall pay Her the attention She deserves: 519 when we shall feel disposed to consult Her, She will supply us with the requisites to alleviate both our physical and moral evils: 520 She only punishes us with rigour, when, regardless of Her admonitions, we plunge into excesses that disgrace us.

521 Has the voluptuary any reason to complain of the sharp pains inflicted by the gout, when experience, if you had but attended to its counsels, has so often warned you, 522 that the grossness of sensual indulgence must inevitably amass in your machine those humours which give birth to the agony you so acutely feels? 523 Has the superstitious bigot any cause for repining at the misery of your

uncertain ideas, when an attentive examination of that Nature, you holds of such small account, 524 would have convinced you that the idols under whom you trembles, are nothing but personifications of Herself, disguised under some other name? 525 It is evidently by incertitude, discord, blindness, delirium, She chastises those who refuse to, acknowledge the justice of Her claims.

526 In the mean time, it cannot be denied, that a pure Theism, or what is called Natural Religion, may not be preferable to superstition, 527 in the same manner as reform has banished many of the abuses of those countries who have embraced it; 528 but there is nothing short of an unlimited and inviolable liberty of thought, that can permanently assure the repose of the mind. 529 The opinions of people are only dangerous when they are restrained, or when it is imagined necessary to make others think as we ourselves think. 530 No opinions, not even those of superstition itself, would be dangerous, if the superstitious did not think themselves obliged to enforce their adoption, or had not the power to persecute those who refused. 531 It is this prejudice, which, for the benefit of humankind, it is essential to annihilate; 532 and if the thing be not achievable, then the next object which philosophy may reasonably propose to itself, will be to make the depositaries of power feel 533 that they never ought to permit their subjects to commit evil for either superstitious or religious opinions.

534 In this case, wars would be almost unheard of amongst humans: 535 instead of beholding the melancholy spectacle of human cutting the throat of own fellow human, because this cannot see with own eyes, 536 we shall witness you essentially labouring to your own happiness by promoting that of your neighbour; cultivating the earth in peace; quietly bringing forth the productions of Nature, 537 instead of puzzling your brain with theological disputes, which can never be of the smallest advantage, except to the priests. 538 It must be a self-evident

truth, that an argument by people, upon that which is not accessible to human, could only have been invented by knaves, 539 who, like the professors of legerdemain, were determined to riot luxuriously on the ignorance and credulity of humankind.

EXAMINATION OF THE ADVANTAGES WHICH RESULT FROM MAN'S NOTIONS ON THE DIVINITY

Paul Henri Thiery (Baron D'Holbach)

51 The slender foundation of those ideas which people form to themselves of their gods, must have appeared obvious in what has preceded; 2 the proofs which have been offered in support of the existence of immaterial substances, have been examined; 3 the want of harmony that exists in the opinions upon this subject, which all concur in agreeing to be equally impossible to be known to the inhabitants of the earth, has been shown; 4 the incompatibility of the attributes with which, theology has clothed incorporeity, has been explained.

5 It has been proved, that the idols which human sets up for adoration, have usually had their birth, either in the bosom of misfortune, 6 when ignorance was at a loss to account for the calamities of the earth upon natural principles, 7 or else have been the shapeless fruit of melancholy, working upon an alarmed mind, coupled with enthusiasm and an unbridled imagination. 8 It has been pointed out how these prejudices, transmitted by tradition from father to son, grafting themselves upon infant minds, 9 cultivated by education, nourished by fear, corroborated by habit, have been maintained by authority; perpetuated by example. 10 In short, everything must have distinctly evidenced to us, that the ideas of the gods, so generally diffused over the earth, has been little more than an universal delusion of the human race. 11 It remains now to examine if this error has been useful.

12 It needs little to prove error can never be advantageous for humankind; 13 it is ever founded upon human ignorance, which is itself an acknowledged evil; 14 it springs out of the blindness of human mind to acknowledged truths, and your want of experience, which it must be admitted are prejudicial to your interests: 15 the more importance, therefore, you shall attach to these errors, the more fatal will be the consequences resulting from their adoption. 16 Bacon, the illustrious sophist, who first brought philosophy out of the schools, had great reason when he said, "The worst of all things is deified error." 17 Indeed, the mischiefs springing from superstition or religious errors, have been, and always will be, the most terrible in their consequences--the most extensive in their devastation. 18 The more these errors are respected, the more play they give to the passions; 19 the more value is attached to them, the more the mind is disturbed; 20 the more they are insisted upon, the more irrational they render those, who are seized with the rage for proselytism; 21 the more they are cherished, the greater influence they have on the whole conduct of our lives. 22 Indeed, there can be but little likelihood that you who renounces your reason, in the thing which you considers as most essential to your happiness, will listen to it on any other occasion.

23 The slightest reflection will afford ample proof to this sad truth: 24 in those fatal notions which human has cherished on this subject, are to be traced the true sources of all those prejudices, 25 the fountain of all those sorrows, to which you are the victim. 26 Nevertheless, as we have elsewhere said, utility ought to be the only standard, the uniform scale, by which to form a judgment 27 on either the opinions, the institutions, the systems, or the actions of intelligent beings; 28 it is according to the measure of happiness which these things procure for us, that we ought either to cover them with our esteem, or expose them to our contempt. 29 Whenever they are useless it is our duty to despise them;

as soon as they become pernicious, it is imperative to reject them; 30 reasons imperiously prescribes that our detestation should be commensurate with the evils which they cause.

31 Taking these principles for a land-mark, which are founded on our nature, which must appear incontestable to every reasonable being, 32 with experience for a beacon, let us coolly examine the effects which these notions have produced on the earth. 33 We have already, in more than one part of the work, given a glimpse of the doctrine of that morals, which having only for object the preservation of human, 34 and his conduct in society, can have nothing, in common with imaginary systems: 35 it has been shown, that the essence of a sensitive, intelligent, rational being, properly meditated, would discover motives competent to moderate the fury of your passions-- 36 to induce you to resist your vicious propensities-- to make you fly criminal habits-- 37 to invite you to render yourself useful to those beings for whom your own necessities have a continual occasion; 38 thus, to endear yourself to your fellow mortals, to become respectable in your own esteem. 39 These motives will unquestionably be admitted to possess more solidity, to embrace greater, potency, to involve more truth, than those which are borrowed from systems that want stability; 40 that assume more shapes than there are languages; that are not tangible to the tact of humanity; 41 that must of necessity present a different perspective to all who shall view them through the medium of prejudice.

42 From what has been advanced, it will be felt that education, which should make human in early life contract good habits, adopt favourable dispositions, 43 fortified by a respect for public opinion, invigorated by ideas of decency, strengthened by wholesome laws, 44 corroborated by the desire of meriting the friendship of others, stimulated by the fear of losing own esteem, 45 would be fully adequate to accustom you to a laudable conduct, 46 amply sufficient to divert you

from even those secret crimes, from which you are obliged to punish yourself by remorse; 47 which costs you the most incessant labour to keep concealed, by the dread of that shame, which must always follow their publicity.

48 Experience demonstrates in the clearest manner, that the success of a first crime disposes you to commit a second; 49 impunity leads on to the third, this to a lamentable sequel that frequently closes a wretched career with the most ignominious exhibition; 50 thus the first delinquency is the commencement of a habit: there is much less distance from this to the hundredth, than from innocence to criminality: 51 the person, however, who lends the self to a series of bad actions, under even the assurance of impunity, is most woefully deceived, 52 because you cannot avoid castigating yourself: moreover, you cannot know at what point of iniquity you shall stop.

53 It has been shown, that those punishments which society, for its own preservation, has the right to inflict on those who disturb its harmony, 54 are more substantive, more efficacious, more salutary in their effects, than all the distant torments held forth by the priests; 55 they intervene a more immediate obstacle to the stubborn propensities of those obdurate wretches, 56 who, insensible to the charms of virtue, are deaf to the advantages that spring from its practice, 57 than can be opposed by the denunciations, held forth in an hereafter existence, which you are at the same moment taught may be avoided by repentance, 58 that shall only take place when the ability to commit further wrong has ceased.

59 In short, one would be led to think it obvious to the slightest reflection, that politics, founded upon the nature of human, upon the principles of society, 60 armed with equitable laws, vigilant over morals, faithful in rewarding virtue, constant in visiting crime, 61 would be more suitable to clothe ethics with respectability, to throw a sacred mantle over moral goodness, to lend stability to public virtue, 62 than any authority that can be derived from contested systems,

the conduct of whose professors frequently disgrace the doctrines they lay down, 63 which after all seldom do more than restrain those whose mildness of temperament effectually prevents them from running into excess; 64 those who, already given to justice, require no coercion. 65 On the other hand, we have endeavoured to prove that nothing can be more absurd, nothing actually more dangerous, than attributing human qualities to the Divinity 66 which cannot but choose to find themselves in a perpetual contradiction.

67 Plato has said "that virtue consists in resembling God." 68 But how is human to resemble a being, who, it is acknowledged, is incomprehensible to humankind-- 69 who cannot be conceived by any of those means, by which you are alone capable of having perceptions? 70 If this being, who is shown to human under such various aspects, who is said to owe nothing to His creatures, is the author of all the good, as well as all the evil that takes place, 71 how can He be the model for the conduct of the human race living together in society? 72 At most you can only follow one side of the character, because among your fellows, you alone is reputed virtuous who does not deviate in your conduct from justice; 73 who abstains from evil; who performs with punctuality those duties you owes to your fellows. 73 If it be taken up, and insisted God is not the author of the evil, only of the good, I say very well: that is precisely what I wanted to know; 74 you thereby acknowledge God is not the author of everything; 75 we are no longer at issue; you are inconclusive to your own premises, consequently ought not to demand an implicit reliance on what you choose to assert.

76 But, replies the subtle theologian, that is not the affair; you must seek it in the creed I have set forth-- in the religion of which I am a pillar. 77 Very good: Is it then actually in the system of fanatics, that human should draw up own ideas of virtue? 78 Is it in the doctrines which these codes hold forth, that you are to seek for a model? 79 Alas! do they not

portray their idols: under the most unwholesome colours; 80 do they not represent them as following their caprice in everything, who love or hate, who choose or reject, who approve or condemn according to their whim, 81 who delight in carnage, who send discord amongst people, who act irrationally, who commit wantonness, 82 who sport with their feeble subjects, who lay continual snares for them, who rigorously interdict the use of their reason? 83 What, let us seriously ask, would become of morality, if people proposed to themselves such portraits for models!

84 It was, however, for the most part, systems of this temper that nations adopted. 85 At was in consequence of these principles that what has been called religion in most countries, was far removed from being favourable to morality; 86 on the contrary, it often shook it to its foundation--frequently left no vestige of its existence. 87 It divided human, instead of drawing closer the bonds of union; 88 in the place of that mutual love, that reciprocity of succour, which ought ever to distinguish human society, it introduced hatred and persecution; 89 it made them seize every opportunity to cut each other's throat for speculative opinions, equally irrational; 90 it engendered the most violent heart-burnings-- the most rancorous animosities-- the most sovereign contempt. 91 The slightest difference in their received opinions rendered them the most mortal enemies; 92 separated their interests for ever; made them despise each other; and seek every means to render their existence miserable.

93 For these theological conjectures, nations become opposed to nations; the sovereign frequently armed the self against their subjects; 94 subjects waged war with their sovereign; citizens gave activity to the most sanguinary hostility against each other; 95 parents detested their offspring; children plunged the pointed steel, the barbed arrow, into the bosoms of those who gave them existence; 96 husbands and wives disunited, became the scourges of each other; 97 relations forgetting the

ties of consanguinity, tore each other to pieces, or else reciprocally consigned them to oblivion; 98 all the bonds of society were rent asunder; the social compact was broken up; society committed suicide: 99 whilst in the midst of this fearful wreck-- regardless of the horrid shrieks called forth by this dreadful confusion-- 100 unmindful of the havock going forward on all sides-- each pretended that one conformed to the views of own idol, detailed to one by own priest-- fulminated by the oracles. 101 Far from making the self any reproach, for the misery one spread abroad, each lauded own individual conduct; gloried in the crimes one committed in support of own sacred cause.

102 The same spirit of maniacal fury pervaded the rites, the ceremonies, the customs, which the worship, adopted by superstition, placed so much above all the social virtues. 103 In one country, tender mothers delivered up their children to moisten with their innocent blood the altars of their idols; 104 in another, the people assembled, performed the ceremony of consolation to their deities, for the outrages they committed against them, and finished by immolating to their anger human victims; 105 in another, a frantic enthusiast lacerated own body, condemned the self for life to the most rigorous tortures, to appease the wrath of own gods.

106 The Jupiter of the Pagans was a lascivious monster; the Moloch of the Phenicians was a cannibal; 107 the savage idol of the Mexican requires thousands of mortals to bleed on his shrine, in order to satisfy his sanguinary appetite. 108 Such are the models superstition holds out to the imitation of human; 109 is it then surprising that the name of these despots became the signal for mad-brained enthusiasm to exercise its outrageous fury; 110 the standard under which cowardice wreaked its cruelty; the watchword for the inhumanity of nations to muster their barbarous strength; 111 a sound which spreads terror wherever its echo could reach; 112 a continual pretext for the most barefaced breaches of public decorum; for the

most shameless violation of the moral duties?

113 It was the frightful character people gave of their gods, that banished kindness from their hearts-- virtue from their conduct-- felicity from their habitations-- reason from their mind: 114 almost every where it was some idol, who was disturbed by the mode in which unhappy mortals thought; 115 this armed them with poignards against each other; made them stifle the cries of Nature; rendered them barbarous to themselves; atrocious to their fellow creatures: 116 in short, they became irrational, breathed forth vengeance, outraged humanity, 117 every time that, instigated by the priest, they were inclined to imitate the gods of their idolatry, to display their zeal, to render themselves acceptable in their temples.

118 It is not, then, in such systems, human ought to seek either for models of virtue, or rules of conduct suitable to live in society. 119 He needs human morality, founded upon His own nature; built upon invariable experience; submitted to reason. 120 The ethics of superstition will always be prejudicial to the earth; 121 cruel masters cannot be well served, but by those who resemble them: 122 what then becomes of the great advantages which have been imagined resulted to human, from the notions which have been unceasingly infused into you of your gods?

123 We see that almost all nations acknowledge them; 124 yet, to conform themselves to their views, they trampled underfoot the clearest rights of Nature-- the most evident duties of humanity; 125 they appeared to act as if it was only by madness the most incurable-- by folly the most preposterous-- 126 by the most flagitious crimes, committed with an unsparing hand, that they hoped to draw down upon themselves the favour of heaven-- 127 the blessings of the sovereign intelligence they so much boast of serving with unabated zeal; with the most devotional fervour; with the most unlimited obedience.

128 As soon, therefore, as the priests give them to understand their deities command the commission of crime,

or whenever there is a question of their respective creeds, 129 although they are wrapt in the most impenetrable obscurity, they make it a duty with themselves to unbridle their rancour-- to give loose to the most furious passions; 130 they mistake the clearest precepts of morality; 131 they credulously believe the remission of their own sins will be the reward of their transgressions against their neighbour. 132 Would it not be better to be an inhabitant of Soldania in Africa, where never yet form of worship entered, or the name of God resounded, 133 than thus to pollute the land with superstitious castigation-- with the enmity of priests against each other?

134 Indeed, it is not generally in those revered mortals, spread over the earth to announce the oracles of the gods, that will be found the most sterling virtues. 135 These people, who think themselves so enlightened, who call themselves the ministers of heaven, frequently preach nothing but hatred, discord, and fury in its name: 136 the fear of the gods, far from having a salutary influence over their own morals, far from submitting them to a wholesome discipline, 137 frequently do nothing more than increase their avarice, augment their ambition, inflate their pride, extend their covetousness, render them obstinately stubborn, and harden their hearts.

138 We may see them unceasingly occupied in giving birth to the most lasting animosities, by their unintelligible disputes. 139 We see them hostilely wrestling with the sovereign power, which they contend is subordinate to their own. 140 We see them arm the chiefs of nations against the legitimate magistrates; 141 distribute to the credulous multitude the most mortal weapons, to massacre each other in the prosecution of those futile controversies, 142 which sacerdotal vanity clothes with the most interesting importance. 143 Do these people, who advance the beauty of their theories, who menace the people with eternal vengeance, avail themselves of their own marvellous

notions 144 to moderate their pride-- to abate their vanity-- to lessen their cupidity-- to restrain their turbulence-- to bring their vindictive humours under control?

145 Are they, even in those countries where their empire is established upon pillars of brass, fixed on adamantine rocks, decorated with the most curious efforts of human ingenuity-- 146 where the sacred mantle of public opinion shields them with impunity-- 147 where credulity, planted in the hot-bed of ignorance, strikes the roots of their authority into the very centre of the earth; 148 are they, I would ask, the enemies to debauchery, the foes to intemperance, the haters of those excesses which they insist a severe God interdicts to His adorers? 149 On the contrary, are they not seen to be emboldened in crime; intrepid in iniquity; committing the most shameful atrocities; giving free scope to their irregularities; 150 indulging their hatred; glutting their vengeance; exercising the most savage cruelties on the miserable victims to their cowardly suspicion?

151 In short, it may be safely advanced, without fear of contradiction, that scarcely any thing is more frequent, than that those people who announce these terrible creeds-- 152 who make people tremble under their yoke-- who are unceasingly haranguing upon the eternity and dreadful nature of their punishments-- 153 who declare themselves the chosen ministers of their oracular laws-- who make all the duties of morality centre in themselves; 154 are those whom superstition least contributes to render virtuous; 155 are people who possess the least milk of human kindness; the fewest feelings of tenderness; 156 who are the most intolerant to their neighbours; the most indulgent to themselves; the most unsociable in their habits; the most licentious in their manners; the most unforgiving in their disposition.

157 In contemplating their conduct, we should be tempted to accredit, that they were perfectly undeceived with respect to the idols whom they serve; 158 that no one was less the dupe to those menaces which they so

solemnly pronounce in their name, than themselves.

159 In the hands of the priests of almost all countries, their divinities resembled the head of Medusa, which, without injuring you who showed it, petrified all others. 160 The priests are generally the most crafty of people, and many among them are substantively wicked. 161 Does the idea of these avenging, these remunerating systems, impose upon some princes of the earth, who found their titles, who rest their power upon them; 162 who avail themselves of their terrific power to intimidate their subjects; 163 to make the people, often rendered unhappy by their caprice, hold them in reverence? 164 Alas! the theological, the supernatural ideas, adopted by the pride of some sovereigns, have done nothing more than corrupt politics-- than metamorphose, them into an abject tyranny. 165 The ministers of these idols, always tyrants themselves, or the cherishers of despots, are unceasingly crying out to monarchs that they are the images of the Divinity. 166 Do they not inform the credulous multitude that heaven is willing they should groan under the most cruel bondage; writhe under the most multifarious injustice; 167 that to suffer is their inheritance; 168 that their princes have the indubitable right to appropriate the goods, dispose of the people, coerce the liberty; command the lives of their subjects? 169 Do not some of these chiefs of nations, thus poisoned in the name of deified idols, imagine that every indulgence of their wayward humour is freely permitted to them? 170 At once competitors, representatives, and rivals of the celestial powers, do they not, in some instances, exercise after their example the most arbitrary despotism? 171 Do they not, in the intoxication into which sacerdotal flattery has plunged them, think that like their idols, they are not accountable to human for their actions, 172 that they owe nothing to the rest of mortals, that they are bound by no bonds but their own unruly will, to their miserable subjects?

173 Then it is evident that it is to theological notions, to the loose flattery of its ministers, that are to be ascribed the despotism, 174 the tyrannical injustice, the corruption, the licentiousness of some princes, and the blindness of those people, to whom in heaven's name they interdict the love of liberty; 175 who are forbid to labour effectually to their own happiness; to oppose themselves to violence, however flagrant; 176 to exercise their natural rights, however conducive to their welfare. 177 These intoxicated rulers, even while adoring their avenging gods, in the act of bending others to their worship, 178 do not scruple to outrage them by their irregularities-- by their want of moral virtue.

179 What morality is this, but that of people who offer themselves as living images, as animated representatives of the Divinity? 180 Are those monarchs, then, who are habitually unjust, who wrest without remorse the bread from the hands of a famished people, 181 to administer to the profligacy of their insatiable courtiers-- to pamper the luxury of the vile instruments of their enormities, atheists? 182 Are, then, those ambitious conquerors, who not contented with oppressing their own slaves, carry desolation, spread misery, deal out death among the subjects of others, atheists? 183 Do we not witness in some of those potentates who rule over nations by divine right,-- a patent of power, which every usurper claims as their own-- 184 ambitious mortals, whose exterminating fury nothing can arrest; with hearts perfectly insensible to the sorrows of humankind; 185 with minds without energy; with souls without virtue; who neglect their most evident duties, with which they do not even deign to become acquainted; 186 powerful people, who insolently set themselves above the rules of equity; knaves who make a sport of honesty? 187 Generally speaking, is there the least sincerity in the alliances which these rulers form among themselves? 188 Do they ever last longer than for the season of their convenience? 189 Do we find substantive virtues adorn those who most abjectly submit

themselves to all the follies of superstition? 190 Do they not tax each other as violators of property-- as faithlessly aggrandising themselves at the expense of their neighbour; 191 in fact, do we not see them endeavouring to surprise, anxious to over-reach, ready to injure each other, without being arrested by the menaces of their creeds, or at all yielding to the calls of humanity? 192 In general, they are too haughty to be humane; too inflated with ambition to be virtuous; 193 they make a code for themselves, which they cannot help violating.

194 Charles the Fifth used to say, "that being a warrior, it was impossible for him to have either conscience or religion." 195 His general, the Marquis de Piscaire, observed, that "nothing was more difficult, than to serve at one and the same time, the god Mars and Jesus Christ." 196 Indeed, nothing can be more opposed to the true spirit of Christianity than the profession of arms; 197 notwithstanding the Christian princes have the most numerous armies, and are in perpetual hostility with each other: 198 perhaps the clergy themselves do not hold forth the most peaceable examples of the doctrine they teach; 199 they sometimes wrangle for tithes, dispute for trifling enjoyments, quarrel for worldly opinion, 200 with as much determined obstinacy, with as, much settled rancour, with as little charity, as could possibly inhabit the bosom of the most unenlightened.

201 Pagan, whose ignorance they despise-- whose superstition they rank as the grossest effort of idolatrous debasement. 202 It might almost admit of doubt whether they would be quite pleased to see the mild maxims of the Evangelists, the true Christian meekness, rigidly followed-- 203 whether they might not think the complete working of their own system would clash with their own immediate interests? 204 Is it a demonstrable axiom that the ministers of the Christian faith do not think soldiers are beings extremely well calculated to give efficacy to their doctrine-- solidity to their advantages-- durability to their

claims? 205 Be this as it may, priests as well as monarchs have occasionally waged war for the most futile interests; impoverished a people from the anti-Christian motives; 206 wrested from each other with all the venom of furies, the bloody remnant of the nations they have laid waste; 207 in fact, to judge by their conduct on certain occasions, it might have been a question if they were not disputing who should have the credit of making the greater number of miserable beings upon earth.

208 At length, either wearied with their own fury, exhausted by their own devouring passions, or compelled by the stern hand of necessity, they have permitted suffering humanity to take breath; 209 they have allowed the miseries concomitant on war, to cease for an instant their devastating havoc; 210 they have made peace in the name of that God, whose decrees, as attested by themselves, they have been so wantonly outraging,-- 211 still ready, however, to violate their most solemn pledges, when the smallest interest could offer them a pretext.

212 Thus it will be obvious, in what manner the idea of the Divinity operates on the priest, as well as upon those who are called His images; 213 who insist they have no account to render but to Him alone.

214 Among these representatives of the Divine Majesty, it is with difficulty during thousands of years we find some few who have equity, sensibility, virtue, or even the most ordinary talent. 215 History points out some of these vicegerents of the Deity, who in the exacerbation of their delirious rage, have insisted upon displacing Him, by exalting themselves into gods; 216 and exacting the most obsequious worship; 217 who have inflicted the most cruel torments on those who have opposed themselves to their madness, and refused to acknowledge the Divinity of their people. 218 These people, whose licentiousness knew no limits, from the impunity which attended their actions, 219 notwithstanding they had learned to despise public opinion, to

set decency at defiance, to indulge in the most shameless vice: 220 in spite of the power they possessed; of the homage they received; of the terror they inspired: 221 although they had learned to counterfeit, with great effect, the whole catalogue of human virtues; 222 found it impossible, even with the addition of their enormous wealth, wrenched from the necessities of labourious honesty, to counterfeit the animating blush, 223 which modest merit brings forth, when eulogised by some happy being whose felicity they have occasioned, 224 by following the great law of Nature-- which says, "love thy neighbour as thyself." 225 On the contrary, we see them grow listless with satiety; disgusted with their own inordinate indulgences; 226 obliged to recur to strange pleasures, to awaken their benumbed faculties; 227 to run headlong into the most costly follies, in the fruitless attempt to keep up the activity of their souls, 228 the spring of which they had for ever relaxed, by the profligacy of their enjoyment.

229 History, although it describes a multitude of vicious rulers, whose irregular propensities were of the most mischievous consequence to the human race, 230 nevertheless, shows us but few who have been atheists. 231 The annals of nations, on the contrary, offer to our view great numbers of superstitious princes, 232 governed by their mistresses, led by unworthy favourites, leagued with priests, who passed their lives plunged in luxury; 233 indulging the most effeminate pursuits; following the most childish pleasures; pleased with ostentatious show; 234 slaves even to the fashion of the vestments that covered them; but strangers to every humanly virtue; 235 insensible to the sorrows of their subjects; although uniformly good to their hungry courtiers, 236 invariably kind to those cringing sycophants who surrounded their people, and poisoned their ears with the most fulsome flattery: 237 in short, superstitious persecutors, who, to render themselves acceptable to their priests, to expiate their own shameful irregularities, added to all their other

vices that of tyrannising over the mind, 238 of fettering the conscience, of destroying their subjects for their opinions, when they were in hostility with their own received doctrines.

239 Indeed, superstition in princes frequently allied itself with the most horrid crimes; 240 they have almost all professed religion, although very few of them have had a just knowledge of morality-- have practiced any useful substantive virtue. 241 Superstitious notions, on the contrary, often serve to render them more blind, to augment their evil inclinations; 242 to set them at a greater distance from moral goodness. 243 They for the most part believe themselves assured of the favour of heaven; 244 they think they faithfully serve their gods, that the anger of their divinities is appeased, if for a short season they show themselves attached to futile customs-- 245 lend themselves to absurd rites-- perform some ridiculous duties, which superstition imposes on them, 246 with a view to obtain their assistance in the prosecution of its own plans, very rarely in strict unison with their immediate interest.

247 Nero, the cruel, sanguinary, matricidal Nero, his hands yet reeking with the blood of that unfortunate being who had borne him in her womb, 248 who had, with agonising pains, given the monster to the world that plunged the dagger in her heart, was desirous to be initiated into the Eleusinian Mysteries. 249 The odious Constantine himself, found in the priests, accomplices disposed to expiate his crimes. 250 The infamous Philip, whose ungovernable ambition caused him to be called the daemon of the south, whilst he assassinated his wife and son, 251 caused the throats of the wretched Batavians to be cut for their religious opinions. 252 It is thus, that the priests of superstition sometimes persuade sovereigns they can atone for crimes, by committing others of a more atrocious kind-- of an increased magnitude.

253 It would be fair to conclude, from the conduct of so many princes, who had so much superstition, but so slender a portion of virtue, 254 that

the notion of their gods, far from being useful to them, only served to render them more corrupt-- to make them more abominable than they already were; 255 that the idea of an avenging power, placed in the perspective of futurity, imposed but little restraint on the turbulence of deified tyrants, 256 who were sufficiently powerful not to fear the reproaches of their subjects-- who had the insensibility to be deaf to the censure of their fellows-- 257 who were gifted with an obduracy of soul, that prevented their having compassion for the miseries of humankind, from whom they fancied themselves so pre-eminently distinguished; 258 which, in fact, they were, if crime can be allowed for the standard of distinction.

259 Neither heaven nor earth furnishes a balsam of sufficient efficacy to heal the inveterate wounds of beings cankered to this degree: 260 for such chronic diseases, there is "no balm in Gilead:" 261 there is no curb sufficiently coercive to rein in the passions, to which superstition itself gives activity; which only makes them more unruly; renders them more inveterately rash. 262 Whenever people flatter themselves with easily expiating their sins-- 263 when they soothe themselves with the consolatory idea of appeasing the anger of the gods by a show of earnestness, 264 they then deliver themselves up, with the most unrestrained freedom, to the bent of their criminal pursuits. 265 The most dissolute people are frequently in appearance extremely attached to superstition: 266 it furnishes them with a means of compensating by ceremonies, that of which they are deficient in morals: 267 it is much easier for them to adopt a faith, to believe in a doctrine, to conform themselves to certain rituals, 268 than to renounce their habits, resist their passions, or relinquish the pursuit of that pleasure, 269 which results to unprincipled minds from the prosecution of the most diabolical schemes.

270 Under chiefs, depraved even by superstition, nations continued necessarily to be corrupted. 271 The great conformed themselves to the

vices of their masters; 272 the example of these distinguished people, whom the uninformed erroneously believe to be happy, was followed by the people; 273 courts thus became the sinks from whence issued the epidemic contagion of licentious indulgence. 274 The law only held forth pictures of honesty; 275 the dispensers of jurisprudence were partial, partook of the mania of the times, were labouring under the general disease; 276 Justice suffered her balance to rust, occasionally removed her bandage, although she always wore it in the presence of the poor; 277 genuine ideas of equity had grown into disuse; 278 distinct notions of right and wrong became troublesome and unfashionable; 279 education was neglected; it served only to produce prejudiced beings, grounded in ignorance-- 280 devotees, always ready to injure themselves-- fanatics, eager to show their zeal ever willing to annoy their unfortunate neighbours.

281 Superstition, sustained by tyranny, ousted every other feeling, hoodwinked its destined victims, rendered those tractable whom it had the intention to despoil. 282 Whoever doubts of these truisms, has only to turn over the pages of history, you will find myriads of evidence to much more than is here stated. 283 Machiavel, in his Political Discourses upon Titus Livius, labours the point hard, to show the utility of superstition to the Roman Republic: 284 unfortunately, however, the examples he brings forward in its support, incontestably prove that none but the senate profited by the infatuation of the people, 285 who availed itself of their blindness more effectually to bend them to its yoke.

286 Thus it was that nations, destitute of equitable laws, deficient in the administration of justice, submitted to irrational government, continued in slavery by the monarch, 287 chained up in ignorance by the priest, for want of enlightened institutions, deprived of reasonable education, became corrupt, superstitious, and flagitious. 288 The nature of human, the just interests of society, the real advantage of the sovereign, the true

happiness of the people, once mistaken, were completely lost sight of; 289 the morality of Nature, founded upon the essence of human living in society, was equally unknown; 290 lay buried under an enormous load of prejudice, that no common efforts were competent to remove.

291 It was entirely forgotten that human has wants; that society was formed that you might, with greater security, facilitate the means of satisfying them; 292 that government, to be legitimate, ought to have for object, the happiness--for end, the means of maintaining the indivisibility of the community; 293 that consequently it ought to give activity to springs, full play to motives suitable to have a favourable influence over sensible beings. 294 It was quite overlooked, that virtue faithfully rewarded, vice as regularly visited, had an elastic force, 295 of which the public authorities could efficaciously avail themselves, to determine their citizens to blend their interests; 296 to work out their own felicity, by labouring to the happiness of the body of which they were members. 297 The social virtues were unknown, the 'amor patriae' became a chimera. 298 People thus associated, thus blinded by their superstitious bias, credulously believed their own immediate interest consisted in injuring each other; 299 they were solely occupied with meriting the favour of those people, who fatally accredited the doctrine of clerical flatterers, 300 of silver-toned courtiers, which taught that they were more distinctly interested in injuring the whole.

301 This is the mode in which the human heart has become perverted; here is the genuine source of moral evil; 302 the hot-bed of that epidemical depravity, the cause of that hereditary corruption, the fountain of that inveterate delinquency, which pervaded the earth; 303 rendering the abundance of Nature nothing better than a curse; 304 blasting the fairest prospects of humanity; degrading human below the beast of the forest; sinking your intellectual faculties in the most savage barbarity; 305 rendering you

the vile instrument of lawless ambition; the wretched tool by which the fetters of your species were firmly riveted; 306 obliging you to moisten your harvest with the bitter tears of the most abject slavery.

307 For the purpose of remedying so many crying evils, grown insupportable, recourse was had to new superstitions. 308 Notwithstanding this alone had produced them, it was still imagined, that the menaces of heaven would restrain passions which everything conspired to rouse in all hearts; 309 fatuity persuaded monarchs that ideal, metaphysical barriers, terrible fables, distant phantoms, would be competent to curb those inordinate desires, 310 to rein in that impetuous propensity to crime, that rendered society incommodious to itself; 311 credulity fancied that invisible powers would be more efficacious, than those visible motives that evidently invited mortals to the commission of mischief. 312 Everything was understood to be achieved, by occupying human's mind with gloomy chimeras, with vague, indefinable terrors, with avenging angels; 313 and politics madly believed that its own interests grew out of the blind submission of its subjects, to the ministers of these delusive doctrines.

314 What was the result? Nations had only sacerdotal laws; theological morality; 315 accommodated to the interests of the hierarchy-- suitable to the views of subtle priests: 316 who substituted reveries for realities, opinions for reason, rank fallacies for sterling truths; 317 who made ceremonies supply the place of virtue; 318 a pious blindness supersede the necessity of an enlightened understanding; 319 undermined the sacredness of oaths, and placed fanaticism on the altars of sociability. 320 By a necessary consequence of that confidence which the people were compelled to give to the ministers of superstition, 321 two distinct authorities were established in each state, who were substantially at variance, in continual hostility with each other.

322 The priest fought the sovereign with the formidable weapon of

opinion; 323 it generally proved sufficiently powerful to shake the most established thrones. 324 Thus, although the hierarchy was unceasingly admonishing the people to submit themselves to the divine authority of their sovereigns, because it was derived immediately from heaven, 325 yet, whenever it so happened that the monarch did not repay their advocacy, 326 by blindly yielding their own authority to the supervisance of the priests, 327 these made no scruple of threatening them with loss of their temporalities; 328 fulminated their anathemas, interdicted their dominions, and sometimes went the length of absolving their subjects from allegiance. 329 Superstition, in general, only upholds despotism, that it may with greater certainty direct its blows against its enemies; 330 it overthrows it whenever it is found to clash with its interests. 331 The ministers of invisible powers preach up obedience to visible powers, only when they find these humbly devoted to themselves.

332 Thus the sovereign was never at rest, but when abjectly cringing to their priest, they tractably received their lessons-- 333 lent themselves to their frantic zeal-- and piously enabled them to carry on the furious occupation of proselytism. 334 These priests, always restless, full of ambition, burning with intolerance, frequently excited the sovereign to ravage their own states-- encouraged them to tyranny: 335 when, pursuing this sacerdotal mania, they feared to have outraged humanity, to have incurred the displeasure of heaven, 336 they were quickly reconciled to themselves, upon promise of undertaking some distant expedition, 337 for the purpose of bringing some unfortunate nation within the pale of their own particular creed. 338 When the two rival powers united themselves, morality gained nothing by the junction; 339 the people were neither more happy, nor more virtuous; their morals, their welfare, their liberty, were equally overwhelmed by the combined powers.

340 Thus, superstitious princes always felt interested in the maintenance of theological opinions, 341 which were rendered flattering to their vanity, favourable to their power. 342 Like the grateful perfumes of Arabia, that are used to cover the ill scent of a deadly poison, the priest lulled them into security by administering to their sensualities; 343 these, in return, made common cause with them: 344 fully persuaded that the superstition which they themselves adopted, must be the most wholesome for their subjects, most conducive to their interests, 345 those who refused to receive the boon, thus gratuitously forced upon them, were treated as enemies, 346 held up to public scorn, and rendered the victims of punishment.

347 The most superstitious sovereign became, either politically or through piety, the executioner of one part of own slaves; 348 they were taught to believe it a sacred duty to tyrannise over the mind-- to overwhelm the refractory-- 349 to crush the enemy of their priest, under an idea that they were therefore hostile to their own authority. 350 In cutting the throats of these unfortunate sceptics, they imagined they at once discharged their obligations to heaven, and gave security to their own power. 351 They did not perceive, that by immolating victims to their priest, they in fact strengthened the arm of their most formidable foe-- 352 the real enemy to their authority-- the rival of their greatness-- the least subjected of their subjects.

353 But the prevalence of these false notions, with which both the minds of the sovereign and the people were prepossessed, 354 it was found that everything in society concurred to gratify the avidity, to bolster the pride, to glut the vengeance of the sacerdotal order: 355 everywhere, it was to be observed, that the most turbulent, the most dangerous, the most useless people, were those who were the most amply rewarded. 356 The strange spectacle presented itself, of beholding those who were born the bitterest enemies to sovereign power, cherished by its fostering care--honoured at its hands: 357 the most rebellious subjects were

looked upon as the pillars of the throne; 358 the corrupters of the people were rendered the exclusive masters of education; 359 the least labourious of the citizens were richly rewarded for their idleness-- 360 munificently remunerated for the most futile speculations-- held in respect for their fatal discord-- gorged with benefits for their inefficacious prayers: 361 they swept off the fat of the land for their expiations, so destructive to morals, so calculated to give permanency to crime. 362 Thus, by a strange fatuity, the viper that could, and frequently did, inflict the most deadly sting on the bosom of confiding credulity, 363 was pampered and nourished by the unsuspecting hand of its destined victim.

364 For thousands of years, nations as well as sovereigns were emulously despoiling themselves to enrich the expounders of superstition; 365 to enable them to wallow in abundance: they loaded them with honours, 366 decorated them with titles, invested them with privileges, granted them immunities, 367 for no other purpose than to make them bad citizens, unruly subjects, mischievous beings, who revenged upon society the advantages they had received. 368 What was the fruit that kings and people gathered from their imprudent kindness? What was the harvest these men yielded to their labour? 369 Did princes really become more powerful; were nations rendered more happy; did they grow more flourishing; did people become more rational?

370 No! Unquestionably, the sovereign lost the greater portion of their authority; they were the slave of their priests; 371 and when they wished to preserve the remnant that was left, or to recover some part of what had been wrested from them, 372 they were obliged to be continually wrestling against the people their own indulgence, their own weakness, had furnished with means, to set their authority at defiance: 373 the riches of society were lavished to support the idleness, maintain the splendour, 374 satiate the luxury of the most useless, the

most arrogant, the most dangerous of its members.

375 Did the morals of the people improve under the pastoral care of these guides, who were so liberally rewarded? 376 Alas! the superstitious never knew them, their fanatic creed had usurped the place of every virtue; 377 its ministers, satisfied with upholding the doctrines, with preserving the ceremonies so useful to their own interests, 378 only invented fictitious crimes--multiplied painful penances--instituted absurd customs; 379 to the end, that they might turn even the transgressions of their slaves to their own immediate profit. 380 Every where they exercised a monopoly of expiatory indulgences; they made a lucrative traffic of pretended pardons from above; 381 they established a tariff, according to which crime was no longer contraband, but freely admitted upon paying the customs. 382 Those subjected to the heaviest impost, were always such as the hierarchy judged most inimical to its own stability; 383 you might at a very easy rate obtain permission to attack the dignity of the sovereign, to undermine the temporal power, 384 but it was enormously dear to be allowed to touch even the hem of the sacerdotal garments.

385 Thus heresy, sacrilege, were considered crimes of a much deeper dye, that fixed an indelible stain on the perpetrator, 386 alarmed the mind of the priestly order, much more seriously than the most inveterate villainy, the most determined delinquency, which more immediately involved the true interests of society. 387 Thence the ideas of the people were completely overturned, imaginary crimes terrified them, while real crimes had no effect upon their obdurate hearts. 388 A person, whose opinions were at variance with the received doctrines, whose abstract systems did not harmonise with those of their priests, was more loathed than a corrupter of youth; 389 more abhorred than an assassin; more hated than an oppressor; was held in greater contempt than a robber; was punished with greater rigour than the seducer of innocence.

390 The acme of all wickedness, was to despise that which the priest was desirous should be looked upon as sacred. 391 The celebrated Gordon says, "the most abominable of heresies, is to believe there is any other god than the clergy." 392 The civil laws concurred to aid this confusion of ideas; they inflicted the most serious penalties, 393 punished in the most atrocious manner those unknown crimes which imagination had magnified into the most flagitious actions; 394 heretics, infidels, were brought to the stake, and publicly burnt with the utmost refinement of cruelty; 395 the brain was tortured to find means of augmenting the sufferings of the unhappy victims to sacerdotal fury; 396 whilst calumniators of innocence, adulterers, depredators of every description, knaves of all kinds, were at a trifling cost absolved from their past iniquity, and opened a new account of future delinquency. 397 Under such instructors what could become of youth? The period of juvenility was shamefully sacrificed to superstition.

398 Human, from your earliest infancy, was poisoned with unintelligible notions; 399 fed with mysteries; crammed with fables; drenched with doctrines, in which you was compelled to acquiesce without being able to comprehend. 400 Your brain was disturbed with phantoms, alarmed with chimeras, rendered frantic by visions. 401 Your genius was cramped with puerile pursuits, mechanical devotions, sacred trifles. 402 Superstition at length so fascinated the human mind, made such mere automata of humankind, 403 that the people consented to address their gods in a dialect they did not themselves understand: 404 women occupied their whole lives in singing Latin, without comprehending a word of the language; 405 the people assisted very punctually, without being competent to explain any part of the worship, under an idea that it was taken kindly they should thus weary themselves; 406 that it was sufficient to show their people in the sacred temples, which were beautifully decorated to fascinate their senses.

407 Thus human wasted their most precious moments in absurd customs; spent their life in idle ceremonies; 408 your bead was crowded with sophisms, your mind was loaded with errors; intoxicated with fanaticism, you was the declared enemy to reason; 409 forever prepossessed against truth, the energy of your soul was resisted by shackles too ponderous for its elasticity; 410 the spring gave way, and you sunk into sloth and wretchedness: 411 from this humiliating state you could never again soar; you could no longer become useful either to yourself or to your associates: 412 the importance you attached to your imaginary science, or rather the systematic ignorance which served for its basis, 413 rendered it impossible for the most fertile soil to produce anything but thorns; for the best proportioned tree to yield anything but crabs.

414 Does a superstitious, sacerdotal education, form intrepid citizens, intelligent fathers of families, kind husbands, just masters, faithful servants, loyal subjects, pacific associates? 415 No! it either makes peevish enthusiasts or morose devotees, who are incommodious to themselves, vexatious to others: 416 people without principle, who quickly pour the waters of Lethe over the terrors with which they have been disturbed; who know no moral obligation, who respect no virtue. 417 Thus superstition, elevated above everything else, held forth the fanatical dogma, "Better to obey the gods than humans;" 418 in consequence, human believed you must revolt against your prince, detach yourself from your wife, detest your children, 419 estrange yourself from your friends, cut the throats of your fellow-citizens, every time they questioned the veracity of your faith: 420 in short, a superstitious education, when it had its effect, only served to corrupt the juvenile heart-- 421 to fascinate youthful winds with its pageantry-- to degrade the human soul-- 422 to make human mistake the duties you owed to yourself, your obligations to society, your relations with the beings by whom you was surrounded.

NATURE

423 What advantages might not nations have reaped, if they would have employed on useful objects, those riches, which ignorance has so shamefully lavished on the expounders of superstition; 424 which fatuity has bestowed on the most useless ceremonies? 425 What might not have been the progress of genius, if it had enjoyed those ample remunerations, 426 granted during so many ages to those priests who at all times opposed its elevation? 427 What perfection might not science have attained, what height might not the arts have reached, 428 if they had had the same succours that were held forth with a prodigal hand to enthusiasm and futility? 429 Upon what rocks might not morality have been rested, what solid foundations might not politics have found, with what majestic grandeur might not truth have illumined the human horizon, 430 if they had experienced the same fostering cares, the same animating countenance, the same public sanction, which accompanied imposture-- 431 which was showered upon fanaticism-- which shielded falsehood from the rude attack of investigation-- which gave impunity to its ministers?

432 It is then obvious, that superstitious, theological notions, have not produced any of those solid advantages that have been held forth; 433 if may be doubted whether they were not always, and ever will remain, contrary to healthy politics, opposed to sound morality; 434 they frequently change sovereigns into restless, jealous, mischievous, divinities; 435 they transform their subjects into envious, wicked slaves, 436 who by idle pageantry, by futile ceremonies, by an exterior acquiescence in unintelligible opinions, imagine themselves amply compensated for the evil they commit against each other. 437 Those who have never had the confidence to examine these sublimated opinions; 438 those who feel persuaded that their duties spring out of these abstruse doctrines; 439 those who are actually commanded to live in peace, to cherish each other, to lend mutual assistance, to abstain from evil, and to do good, 440

presently lose sight of these sterile speculations, as soon as present interests, ungovernable passions, inveterate habits, or irresistible whims, hurry them away.

441 Where are we to look for that equity, that union of interest, that peace, that concord, 442 which these unsettled notions, supported by superstition, backed with the full force of authority, promise to the societies placed under their surveillance? 443 Under the influence of corrupt courts, of time-serving priests, who, either impostors or fanatics, are never in harmony with each other, 444 are only to be discerned vicious people, degraded by ignorance-- enslaved by criminal habits-- swayed by transient interests-- guided by shameful pleasures-- 445 sunk in a vortex of dissipation; who do not even think of the Divinity.

446 In despite of their theological ideas, the subtle courtier continues to weave their dark plots, labours to gratify their ambition, seeks to satisfy their avidity, to indulge their hatred, to wreak their vengeance, 447 to give full swing to all the passions inherent to the perversity of their being: 448 maugre that frightful hell, of which the idea alone makes her tremble, the woman of intrigue persists in her amours; continues her harlotry, revels in her adulteries. 449 Notwithstanding their dissipated conduct, their dissolute manners, their entire want of moral principle, 450 the greater part of those who swarm in courts, who crowd in cities, would recoil with horror, if the smallest doubt was exhibited of the truth of that creed which they outrage every moment of their lives.

451 What advantage, then, has resulted to the human race from those opinions, so universal, at the same time so barren? 452 They seem rarely to have had any other kind of influence than to serve as a pretext for the most dangerous passions-- as a mantle of security for the most criminal indulgences. 453 Does not the superstitious despot, who would scruple to omit the least part of the ceremonies of own persuasion, 454 on quitting the altars at which the despot been sacrificing, on leaving the

temple where they have been delivering the oracles and terrifying crime in the name of heaven, 455 return to own vices, reiterate own injustice, increase own political crimes, augment own transgressions against society? 456 Issuing from the sacred fane, their ears still ringing with the doctrines they have heard, 457 the minister returns to own vexations, the courtier to own intrigues, the courtezan to own prostitution, the publican to own extortions, the merchant to own frauds, the trader to own tricks.

458 Will it be pretended that those cowardly assassins, those dastardly robbers, those miserable criminals, whom evil institutions, the negligence of government, the laxity of morals, continually multiply; 459 from whom the laws, in many instances too sanguinary, frequently wrest their existence; 460 will it, I say, be pretended that the malefactors who regularly furnish the gibbets, who daily crowd the scaffolds, are either incredulous or atheists? 461 No! Unquestionably, these unfortunate beings, these wretched outcasts, these children of turpitude, firmly believe in God; 462 His name has been repeated to them from their infancy; they have been informed of the punishment destined for sinners: they have been habituated in early life to tremble at His judgments; 463 nevertheless they have outraged society; their unruly passions, stronger than their fears, not having been coerced by visible motives, have not, for much more cogent reasons, been restrained by those which are invisible: 464 distant, concealed punishments will never be competent to arrest those excesses which present and assured torments are incapable of preventing.

465 In short, does not every day's experience furnish us the lesson, that people, persuaded that an all-seeing Deity views them, hears them, encompasses them, do not on that account arrest their progress when the furore exists, 466 either for gratifying their licentious passions, or committing the most dishonest actions? 467 The same individual who would fear the inspection of the meanest of own fellows, whom the

presence of another person would prevent from committing a bad action, from delivering the self up to some scandalous vice, 468 freely sins, cheerfully lends the self to crime, when you believes no eyes beholds you but those of your God. 469 What purpose, then, does the conviction of the omniscience, the ubiquity, the omnipotence of the Divinity answer, 470 if it imposes much less on the conduct of the human being, than the idea of being overlooked by the least of own fellow humans? 471 You who would not have the temerity to commit a crime, even in the presence of a child, will make no scruple of boldly committing it, when you shall have only your God for a witness. 472 These facts, which are indubitable, ill serve for a reply to those who insist that the fear of God is more suitable to restrain the actions of people, than wholesome laws, with strict discipline. 473 When human believes you have only your God to dread, you commonly permits nothing to interrupt your course.

474 Those people who do not in the least suspect the power of superstitious notions, who have the most perfect reliance on their efficacy, very rarely, however, employ them, 475 when they are desirous to influence the conduct of those who are subordinate to them; when they are disposed to re-conduct them to the paths of reason. 476 In the advice which a father gives to own vicious, criminal son, he rather represents to him the present temporal inconveniences to which his conduct exposes him, than the danger he encounters in offending an avenging God; 477 he points out to him the natural consequences of his irregularities, his health damaged by debaucheries; 478 the loss of his reputation by criminal pursuits; the ruin of his fortune by gambling; the punishments of society. 479 Thus the DEICOLIST himself, on the most important occasions of life, reckons more steadfastly upon the force of natural motives, than upon those supernatural inducements furnished by superstition: 480 the same person, who vilifies the motives that an

atheist can have to do good and abstain from evil, makes use of them yourself on this occasion, because you feels they are the most substantive you can employ.

481 Almost all people believe in an avenging and remunerating God; yet nearly in all countries the number of the wicked bears a larger proportion than that of the good. 482 If the true cause of this general corruption be traced, it will be more frequently found in the superstitious notions inculcated by theology, than in those imaginary sources which the various superstitions have invented to account for human depravity. 483 Human is always corrupt wherever you are badly governed; 484 wherever superstition deifies the sovereign, your government becomes unworthy: this perverted and assured of impunity, necessarily render your people miserable; 485 misery, when it exceeds the point of endurance, as necessarily renders them wicked. 486 When the people are submitted to irrational masters, they are never guided by reason. 487 If they are blinded by priests, who are either deceived or impostors, their reason become useless. 488 Tyrants, when combined with priests, have generally been successful in their efforts to prevent nations from becoming enlightened-- 489 from seeking after truth-- from ameliorating their condition-- from perfectioning their morals; and never has the union smiled upon liberty: 490 the people, unable to resist the mighty torrent produced by the confluence of two such rivers, have usually sunk into the most abject slavery.

491 It is only by enlightening the mass of humankind, by demonstrating truth, that we can promise to render you better; that we can indulge the hope of making you happy. 492 It is by causing both sovereigns and subjects to feel their true relations with each other, that their actual interests will be improved; that their politics will be perfectioned: 493 it will then be felt and accredited, that the true art of governing mortals, the sure method of gaining their affections, is not the art of blinding them, of deceiving

them, or of tyrannising over them. 494 Let us, then, good humorously consult reason, avail ourselves of experience, interrogate Nature; 495 we shall, perhaps, find what is requisite to be done, in order to labour efficaciously to the happiness of the human race. 496 We shall most assuredly perceive, that error is the true source of the evils which embitter our existence; 497 that it is in cheering the hearts, in dissipating those vain phantoms which alarm the ignorant, in laying the axe to the root of superstition, that we can peaceably seek after truth; 498 that it is only in the conflagration of this baneful tree, we can ever expect to light the torch which shall illumine the road to felicity. 499 Then let human study Nature; observe Her immutable laws; 500 let you dive into your own essence; let you cure yourself of your prejudices: 501 these means will conduct you by a gentle declivity to that virtue, without which you must feel you can never be permanently happy in the world you inhabits.

502 If human could once cease to fear, from that moment you would be truly happy. 503 Superstition is a domestic enemy which you always carries within yourself: 504 those who will seriously occupy themselves with this formidable phantom, must be content to endure continual agonies, to live in perpetual inquietude: 505 if they will neglect the objects most worthy of interesting them, to run after chimeras, they will commonly pass a melancholy existence, 506 in groaning, in praying, in sacrificing, in expiating faults, either real or imaginary, which they believe calculated to offend their priests; 507 frequently in their irrational fury they will torment themselves, they will make it a duty to inflict on their own people the most barbarous punishments: 508 but society will reap no benefit from these mournful opinions-- from the tortures of these pious irrationals; 509 because their mind, completely absorbed by their gloomy reveries, their time dissipated in the most absurd ceremonies, will leave them no

opportunity of being really advantageous to the community of which they are members. 510 The most superstitions people are commonly misanthropists, quite useless to the world, and very injurious to themselves: 511 if ever they display energy, it is only to devise means by which they can increase their own affliction; to discover new methods to torture their mind; 512 to find out the most efficacious means to deprive themselves of those objects which their nature renders desirable.

513 It is common in the world to behold penitents, who are intimately persuaded that by dint of barbarous infliction on their own people, by means of a lingering suicide, they shall merit the favour of heaven. 514 Mad-people of this species are to be seen everywhere; superstition has in all ages, in all places, given birth to the most cruel extravagances, to the most injurious follies. 515 If, indeed, these irrational devotees only injure themselves, and deprive society of that assistance which they owe to it, they without doubt do less mischief than those turbulent, zealous fanatics, 516 who, infuriated with their superstitious ideas, believe themselves bound to disturb the world, to commit actual crimes, to sustain the cause of what they denominate the true faith. 517 It not infrequently happens that in outraging morality, the zealous enthusiast supposes you renders yourself agreeable to your God. 518 You makes perfection consist either in tormenting yourself, or in rending asunder, in favour of your fanatical ideas, the most sacred ties that connect mortals with each other.

519 Let us, then, acknowledge, that the notions of superstition, are not more suitable to procure the welfare, to establish the content, to confirm the peace of individuals, than they are of the society of which they are members. 520 If some peaceable, honest, inconclusive enthusiasts, find either comfort or consolation in them, there are millions who, more conclusive to their principles, are unhappy during their whole life; 521 who are perpetually assailed by the most melancholy ideas; to whom

their disordered imagination shows these notions, as every instant involving them in the most cruel punishments. 522 Under such formidable systems, a tranquil, sociable devotee, is a person who has not reasoned upon them. 523 In short, everything serves to prove, that superstitious opinions have the strongest influence over people; 524 that they torment them unceasingly, divide them from their dearest connections, inflame their minds, envenom their passions, render them miserable without ever restraining their actions, 525 except when their own temperament proves too feeble to propel them forward: 526 all this holds forth one great lesson, that superstition is incompatible with liberty, and can never furnish good citizens.

THEOLOGICAL NOTIONS CANNOT BE THE BASIS OF MORALITY

Paul Henri Thiery (Baron D'Holbach)

52 Felicity is the great end of human existence; a supposition therefore, to be actually useful to human, should render you happy. 2 By what parity of reasoning can you flatter yourself that an hypothesis, which does not facilitate your happiness in your present duration, may one day conduct you to permanent bliss? 3 If mortals only sigh, tremble, and groan in this world, of which they have a knowledge, upon what foundation is it they expect a more felicitous existence hereafter, in a world of which they know nothing? 4 If human is everywhere the child of calamity, the victim to necessary evil, the unhappy sufferer under an immutable system, ought you reasonably to indulge a greater confidence in future happiness?

5 On the other hand, a supposition which should throw light on everything, which should supply an easy solution to all the questions to which it could be applied, when even it should not be competent to demonstrate the certitude, would probably be true: 6 but that system which should only obscure the clearest notions, render more

insoluble the problems desired to be resolved by its means, 7 would most assuredly be looked upon as fallacious; as either useless or dangerous. 8 To be convinced of this principle, let us examine, without prejudice, if the theological ideas of the Divinity have ever given the solution to any one difficulty. 9 Has the human understanding progressed a single step by the assistance of this metaphysical science? 10 Has it not, on the contrary, had a tendency to obscure the more certain science of morals? 11 Has it not, in many instances, rendered the most essential duties of our nature problematical? 12 Has it not in a great measure confounded the notions of virtue and vice, of justice and injustice?

13 Indeed, what is virtue, in the eyes of the generality of theologians? They will instantly reply, "that which is conformable to the will of the incomprehensible beings who govern Nature." 14 But may it not be asked, without offence to the individual opinions of any one, what are these beings, of whom they are unceasingly talking, without having the capacity to comprehend them? 15 How can we acquire a knowledge of their will? They will forthwith reply, with a confidence that is meant to strike conviction on uninformed minds, by recounting what they are not, without even attempting to inform us what they are. 16 If they do undertake to furnish an idea of them, they will heap upon their hypothetical beings a multitude, of contradictory, incompatible attributes, 17 with which they will form a whole, at once impossible for the human mind to conceive or else they will refer to oracles, by which they insist their intentions have been promulgated to humankind. 18 If, however, they are requested to prove the authenticity of these oracles, which are at such variance with each other, they will refer to miracles in support of what they assert: 19 these miracles, independent of the difficulty there must exist to repose in them our faith, when, as we have seen, they are admitted even by the theologians themselves, 20 to be contrary to the intelligence, the immutability, to the omnipotency of

their immaterial substances, 21 are, moreover, warmly disputed by each particular sect, as being impositions, practised by the others for their own individual advantage. 22 As a last resort, then, it will be necessary to accredit the integrity, to rely on the veracity, to rest on the good faith of the priests, who announce these oracles.

23 On this again, there arises two almost insuperable difficulties, in the first place, who shall assure us of their actual mission? 24 Are we quite certain none of them may be mistaken? How shall we be justified in giving credence to their powers? 25 Are they not these priests themselves, who announce to us that they are the infallible interpreters of a being whom they acknowledge they do not at all know? 26 In the second place, which set of these oracular developments are we to adopt? 27 For to give currency to the whole, would, in point of fact, annihilate them entirely; seeing, that no two of them run in unison with each other. 28 This granted, the priests, that is to say, people extremely suspicious, but little in harmony with each other, will be the arbiters of morality; 29 they will decide-- according to their own uncertain knowledge, after their various passions, in conformity to the different perspectives under which they view these things,-- on the whole system of ethics; 30 upon which absolutely rests the repose of the world-- the sterling happiness of each individual. 31 Would this be a desirable state? would it be that from which humanity has the best founded prospect of that felicity, which is the desired object of your research?

32 Again; do we not see that either enthusiasm or interest is the only standard of their decisions? That their morals are as variable as their caprice? 33 Those who listen to them, very rarely discover to what line they will adhere. 34 In their various writings, we have evidence of the most bitter animosities; we find continual contradictions; endless disputes upon what they themselves acknowledge to be the most essential points; 35 upon those premises, in the substantive proof of which their

whole system depends; 36 the very beings they depict as their source of their various creeds, are portrayed as variable as themselves; as frequently changing their plans as these are their arguments. 37 What results from all this to a rational person? It will be natural for you to conclude, that neither inconstant gods, nor vacillating priests, whose opinions are more fluctuating than the seasons, can be the proper models of a moral system, 38 which should be as regular, as determinate, as invariable as the laws of Nature Herself; as that eternal march, from which we never see Her derogate. 39 No! Arbitrary, inconclusive, contradictory notions, abstract, unintelligible speculations, can never be the sterling bases of the ethical science! 40 They must be evident, demonstrable principles, deduced from the nature of human, founded upon your wants, inspired by rational education, rendered familiar by habit, made sacred by wholesome laws, 41 that will flash conviction on our mind, render systems useful to humankind, make virtue dear to us-- 42 that will people nations with honest people-- fill up the ranks with faithful subjects-- crowd them with intrepid citizens.

43 Incomprehensible beings can present nothing to our imagination, save vague ideas, which will never embrace any common point of union amongst those who shall contemplate them. 44 If these beings are painted as terrible, the mind is led astray; if changeable, it always precludes us from ascertaining the road we ought to pursue. 45 The menaces held forth by those, who, in despite of their own assertions, say they are acquainted with the views, with the determination of these beings, will seldom do more than render virtue unpleasant; 46 fear alone will then make us practise with reluctance, that which reason, which our own immediate interest, ought to make us execute with pleasure. 47 The inculcation of terrible ideas will only serve to disturb honest people, without in the least arresting the progress of the profligate, or diverting the course of the flagitious: 48 the greater number of people,

when they shall be disposed to sin, to deliver themselves up to vicious propensities, will cease to contemplate these terrific ideas, will only behold a merciful God, 49 who is filled with goodness, who will pardon the transgressions of their weakness. 50 Human never views things but on that side which is most conformable to own desires.

51 The goodness of God cheers the wicked; His rigour disturbs the honest person. 52 Thus, the qualities with which theology clothes its immaterial substances, themselves turn out disadvantageous to sound morality. 53 It is upon this infinite goodness that the most corrupt people will have the audacity to reckon, when they are either hurried along by crime, or given up to habitual vice. 54 If, then, they are reminded of their criminal courses, they reply, "God is good, His mercy is infinite, His clemency boundless:" 55 thus it may be said that religion itself is pressed into the service of vice, by the children of turpitude. 56 Superstition, above all, rather abets crime than represses it, by holding forth to mortals that by the assistance of certain ceremonies, the performance of certain rites, the repetition of certain prayers, aided by the payment of certain sums of money, 57 they can appease the anger of their gods, assuage the wrath of heaven, wash out the stains of their sins, and be received with open arms into the happy number of the elect-- be placed in the blissful abodes of eternity. 58 In short, do not the priests of superstition universally affirm, that they possess infallible secrets, for reconciling the most perverse to the pale of their respective systems?

59 It must be concluded from this, that however these systems are viewed, in whatever manner they are considered, they cannot serve for the basis of morality, which in its very nature is formed to be invariably the same. 60 Irascible systems are only useful to those who find an interest in terrifying the ignorance of humankind, that they may advantage themselves of your fears-- profit by your expiations. 61 The nobles of the earth, who are frequently people not

gifted with the most exemplary morals-- 62 who do not on all occasions exhibit the most perfect specimens of self-denial-- 63 who would not, perhaps, be at all times held up as mirrors of virtue, 64 will not see these formidable systems, when they shall be inclined to listen to their passions; to lend themselves to the indulgence of their unruly desires: 65 they will, however, feel no repugnance to make use of them to frighten others, to the end that they may preserve unimpaired their superiority; 66 that they may keep entire their prerogatives; that they may more effectually bind them to servitude. 67 Like the rest of humankind, they will see their God under the traits of His benevolence; 68 they will always believe Him indulgent to those outrages they may commit against their fellows, provided they show due respect for Him themselves: 69 superstition will furnish them with easy means to turn aside His Wrath; its ministers seldom omit a profitable opportunity, to expiate the crimes of human nature.

70 Morality is not made to follow the caprices of the imagination, the fury of the passions, the fluctuating interests of people: 71 it ought to possess stability; to be at all times the same, for all the individuals of the human race; 72 it ought neither to vary in one country, nor in one race from another: 73 neither superstition nor religion, has a privilege to make its immutability subservient to the changeable laws of their systems. 74 There is but one method to give ethics this solidity; it has been more than once pointed out in the course of this work: 75 it is only to be founded upon the nature of human, bottomed upon your duties, rested upon the relations subsisting between intelligent beings, 76 who are in love with their happiness, who are occupied with their own preservation, who live together in society that they may with greater facility ascertain these ends. 77 In short we must take for the basis of morality the necessity of things.

78 In weighing these principles, which are self evident, confirmed by constant experience, approved by

reason, drawn from Nature Herself, we shall have an undeviating tone of conduct; a sure system of morality, that will never be in contradiction with itself. 79 Human will have no occasion to recur to theological speculations to regulate own conduct in the visible world. 80 We shall then be capacitated to reply to those who pretend that without them there can be no morality. 81 If we reflect upon the long tissue of errors, upon the immense chain of wanderings, that flow from the obscure notions these various systems hold forth-- of the sinister ideas which superstition in all countries inculcates; 82 it would be much more conformable to truth to say, that all sound ethics, all morality, either useful to individuals or beneficial to society, is totally incompatible with systems which never represent their gods but under the form of absolute monarchs, whose good qualities are continually eclipsed by dangerous caprices. 83 Consequently, we shall be obliged to acknowledge, that to establish morality upon a steady foundation, we must necessarily commence by at least quitting those chimerical systems 84 upon which the ruinous edifice of supernatural morality has hitherto been constructed, which during such a number of ages, has been so uselessly preached up to a great portion of the inhabitants of the earth.

85 Whatever may have been the cause that placed human in own present abode, that gave you the faculties you possesses; 86 whether the human species be considered as the work of Nature, or whether it be supposed that you owes your existence to an intelligent being, distinguished from Nature; 87 the existence of human, such as you are, is a fact; we behold in you a being who thinks, who feels, who has intelligence, who loves the self, who tends to your own conservation, 88 who in every moment of your duration strives to render your existence agreeable; 89 who, the more easily to satisfy own wants and to procure yourself pleasure, congregates in society with beings similar to yourself; 90 of whom your conduct can either conciliate the

favour, or draw upon you the disaffection. 91 It is, then, upon these general sentiments, inherent in your nature, which will subsist as long as your race shall endure, that we ought to found morality; which is only a science embracing, the duties of people living together in society.

92 These duties have their spring in our nature, they are founded upon our necessities, because we cannot reach the goal of happiness, if we do not employ the requisite means: these means constitute the moral science. 93 To be permanently felicitous, we must so comport ourselves as to merit the affection, so act as to secure the assistance of those beings with whom we are associated; 94 these will only accord us their love, lend us their esteem, aid us in our projects, labour to our peculiar happiness, but in proportion as our own exertions shall be employed for their advantage. 95 It is this necessity, flowing naturally out of the relations of humankind, that is called MORAL OBLIGATION. 96 It is founded upon reflection, rested upon those motives competent to determine sensible, intelligent beings, to pursue that line of conduct, which in best calculated to achieve that happiness towards which they are continually verging. 97 These motives in the human species, never can be other than the desire, always regenerating, of procuring good and avoiding evil. 98 Pleasure and pain, the hope of happiness, or the fear of misery, are the only motives suitable to have an efficacious influence on the volition of sensible beings. 99 To impel them towards this end, it is sufficient these motives exist and be understood to have a knowledge of them, it is only requisite to consider our own constitution: 100 according to this, we shall find we can only love those actions, approve that conduct, from whence result actual and reciprocal utility; this constitutes VIRTUE. 101 In consequence, to conserve ourselves, to make our own happiness, to enjoy security, we are compelled to follow the routine which conducts to this end; 102 to interest others in our own preservation, we are obliged to display an interest in theirs; 103 we

must do nothing that can have a tendency to interrupt that mutual co-operation which alone can lead to the felicity desired. Such is the true establishment of moral obligation.

104 Whenever it is attempted to give any other basis to morality than the nature of human, we shall always deceive ourselves; none other can have the least stability; none can be more solid. 105 Some authors, even of great integrity, have thought, that to give ethics more respectability in the eyes of human, to render more inviolable those duties which your nature imposes on you, 106 it was needful to clothe them with the authority of a being whom they have made superior to Nature-- whom they have rendered more powerful than necessity. 107 Theology, seizing on these ideas, with its own general want of just inference, has in consequence invaded morality; has endeavoured to connect it with its various systems. 108 By some it has been imagined, this union would render virtue more sacred; that the fear attached to invisible powers, who govern Nature, would lend more weight, would give more efficacy to its laws; 109 in short, it has been believed that human, persuaded, of the necessity of the moral system, seeing it united with superstition, would contemplate superstition itself as necessary to own happiness.

110 Indeed it is the supposition that these systems are essential to morality, that sustains the theological ideas-- that gives permanency to the greater part of all the creeds on earth; 111 it is erroneously imagined that without them human would neither understand nor practise the duties you owes to others. 112 This prejudice once established, gives currency to the opinion that the vague ideas growing out of these systems are in such a manner connected with morality, 113 are so linked with the actual welfare of society, that they cannot be attacked without overturning the social duties that bind human to own fellow. 114 It is thought that the reciprocity of wants, the desire of happiness, the evident interests of the community, would be mere skeleton motives, devoid of all active energy, if they

did not borrow their substance from these various systems; 115 if they were not invested with the force derived from these numerous creeds; 116 if they were not clothed with the sanction of those ideas which have been made the arbiters of all things.

117 Nothing, however, is more borne out by the evidence of experience, nothing has more thoroughly impressed itself on the minds of reflecting people, than the danger always arising from connecting truth with fiction; 118 the known with the unknown; the delirium of enthusiasm, with the tranquillity of reason.

119 Indeed what has resulted from the confused alliance, from the marvellous speculations, which theology has made with the most substantive realities? Of mixing up its evanescent conjectures with the confirmed aphorisms of time? 120 The imagination bewildered, has mistaken truth: superstition, by aid of its gratuitous suppositions, has commanded Nature-- made reason bow, under its bulky yoke,-- submitted human to its own peculiar caprices; 121 very frequently in the name of its gods obliged one to stifle own nature, to piously violate the most sacred duties of morality. 122 When these superstitions have been desirous of restraining mortals whom they had previously hood-winked, whom they had rendered irrational, it gave them only ideal curbs, imaginary motives; 123 it substituted unsubstantial causes, for those which were substantive; marvellous supernatural powers, for those which were natural, and well understood; it supplied actual realities, by ideal romances and visionary fables.

124 By this inversion of principle, morality had no longer any fixed basis: 125 Nature, reason, virtue, demonstration, were laid prostrate before the most indefinable systems; were made to depend upon oracular promulgations, which never spake distinctly; 126 indeed, they generally silenced reason, were often delivered by fanatics, which time proved to be impostors; 127 by those who, always adopting the appellation of inspired beings, gave forth nothing but the wanderings of their own delirium,

128 or else were desirous of profiting by the errors which they themselves instilled into humankind. 129 Thus these people became deeply interested in preaching abject submission, non-resistance, passive-obedience, factitious virtues, frivolous ceremonies; 130 in short, an arbitrary morality, conformable to their own reigning passions; frequently prejudicial to the rest of the human race.

131 It was thus, in making ethics flow from these various systems, they in point of fact submitted it to the dominant passions of humans, who had a direct interest in moulding it to their own advantage. 132 In being disposed to found it upon undemonstrative theories, they founded it upon nothing; 133 in deriving it from imaginary sources, of which each individual forms to the self their own notion, generally adverse to that of their neighbour; 134 in resting it upon obscure oracles, always delivered ambiguously, frequently interpreted by people in the height of delirium, sometimes by knaves, who had immediate interests to promote, 135 they rendered it unsteady-- devoid of fixed principle,-- too frequently left it to the mercy of the most crafty of humankind. 136 In proposing to human the changeable creeds of the theologians for a model, they weakened the moral system of human actions; 137 frequently annihilated that which was furnished by Nature; often substituted in its place nothing but the most perplexing incertitude; the most ruinous inconsistency.

138 These systems, by the qualities which are ascribed, to them, become inexplicable enigmas, which each expounds as best suits the self; which each explains after own peculiar mode of thinking; 139 in which the theologian ever finds that which most harmonises with their designs; which they can bend to their own sinister purposes; 140 which they offers as irrefragable evidence of the rectitude of those actions, which at bottom have nothing but their own advantage in view. 141 If they exhort the gentle, indulgent, equitable person, to be good,

compassionate, benevolent; they equally excite the furious, who is destitute of these qualities, to be intolerant, inhuman, pitiless. 142 The morality of these systems varies in each individual; differs in one country from another; 143 in fact, those actions which some people look upon as sacred, which they have learned to consider meritorious, make others shudder with horror--fill them with the most painful recollections. 144 Some see the Divinity filled with gentleness and mercy; others behold Him as full of wrath and fury, whose anger is to be assuaged by the commission of the most shocking cruelties.

145 The morality of Nature is clear, it is evident even to those who outrage it. 146 It is not thus with superstitious morality; this is as obscure as the systems which prescribe it; or rather as fluctuating as the passions, as changeable as the temperaments, of those who expound them; 147 if it was left to the theologians, ethics ought to be considered as the science of all others the most problematical, the most unsteady, the most difficult to bring to a point; 148 it would require the most profound, penetrating genius, the most active, vigorous mind, to discover the principles of those duties human owes to the self, that you ought to exercise towards others; 149 this would render the sources of the moral system attainable by a very small number of individuals; would effectually lock them up in the cabinets of the metaphysicians; place them under the treacherous guardianship of priests: 150 to derive it from those systems, which are in themselves indefinable, with the foundations of which no one is actually acquainted, 151 which each contemplates after their own mode, modifies after their own peculiar ideas, is at once to submit it to the caprice of every individual; 152 it is completely to acknowledge, we know not from whence it is derived, nor whence it has its principles.

153 Whatever may be the agent upon whom they make Nature, or the beings She contains, to depend; with whatever power they may suppose you invested, it is very certain that

human either does, or does not exist; 154 but as soon as your existence is acknowledged, as soon as it is admitted to be what it actually is, when you shall be allowed to be a sensible being living in society, in love with your own felicity, 155 they cannot without either annihilating you, or new modelling you, cause you to exist otherwise than you does. 156 Therefore, according to your actual essence, agreeable to your absolute qualities, conformable to those modifications which constitute you a being, of the human species, 157 morality becomes necessary to you, and the desire of conserving yourself will make you prefer virtue to vice, by the same necessity that you prefers pleasure to pain. 158 If, following up the doctrine of the theologians, "that human hath occasion for supernatural grace to enable you to do good," it must be very injurious to sound principles of morality; 159 because you will always wait for "the call from above," to exercise that virtue, which is indispensable to your welfare. 160 Tertullian, nevertheless says expressly, "wherefore will ye trouble yourselves, seeking after the law of God, whilst ye have that which is common to all the world, and which is written on the tablets of Nature?" 161 To say, that human cannot possess any moral sentiments without embracing the discordant systems offered to your acceptance, is, in point of fact, saying, that you cannot distinguish virtue from vice; 162 it is to pretend that without these systems, human would not feel the necessity of eating to live, would not make the least distinction, would be absolutely without choice in your food: 163 it is to pretend, that unless you are fully acquainted with the name, character, and qualities of the individual who prepares a mess for you, you are not competent to discriminate whether this mess be agreeable or disagreeable, good or bad. 164 You who does not feel yourself satisfied what opinions to adopt, upon the foundation and moral attributes of these systems, 165 or who even formally denies them, cannot at least doubt your own existence- your own functions-- your

own qualities-- your own mode of feeling-- your own method of judging; 166 neither can you doubt the existence of other organised beings similar to yourself; in whom everything discovers to you qualities analogous with your own; 167 of whom you can, by certain actions, either gain the love or incur the hatred-- secure the assistance or attract the ill-will-- merit the esteem or elicit the contempt; 168 this knowledge is sufficient to enable you to distinguish moral good and evil.

169 In short, every person enjoying a well ordered organisation, possessing the faculty of making true experience, will only need to contemplate the self in order to discover what you owes to others: 170 your own nature will enlighten you much more effectually upon your duties, than those systems in which you will consult either your own unruly passions, those of some enthusiast, or those of an impostor. 171 You will allow, that to conserve yourself, to secure your own permanent welfare, you are frequently obliged to resist the blind impulse of your own desires; 172 that to conciliate the benevolence of others, you must act in a mode conformable to their advantage; 173 in reasoning thus, you will find out what virtue actually is; if you puts your theory into practice, you will be virtuous; you will be rewarded for your conduct by the harmony of your own machine; 174 by the legitimate esteem of yourself, confirmed by the good opinion of others, whose kindness you will have secured: 175 if you acts in a contrary mode, the trouble that will ensue, the disorder of your frame, will quickly warn you that nature, thwarted by your actions, disapproves your conduct, which is injurious to yourself; 176 to which you will be obliged to add the condemnation of others, who will hate you. 177 If the wanderings of your mind prevent you from seeing the more immediate consequences of your irregularities, neither will you perceive the distant rewards, the remote punishments, which these systems hold forth; 178 because they will never speak to you so distinctly as your conscience, which will either

reward or punish you on the spot. 179 Theology has never yet known how to give a true definition of virtue: according to it, it is an effort of grace, that disposes human to do that which is agreeable to the Divinity. 180 But what is this grace? How doth it act upon human? How shall we know what is agreeable to a Divinity who is incomprehensible to all people?

181 Everything that has been advanced evidently proves, that superstitious morality is an infinite loser when compared with the morality of Nature, with which, indeed, it is found in perpetual contradiction. 182 Nature invites human to love the self, to preserve your existence, to incessantly augment the sum of your happiness: 183 superstition teaches you to be in love only with formidable doctrines, calculated to generate your dislike; to detest yourself; to sacrifice to your idols your most pleasing sensations--the most legitimate pleasures of your heart. 184 Nature counsels human to consult reason, to adopt it for your guide; superstition portrays this reason as corrupted, as a treacherous director, that will infallibly lead you astray. 185 Nature warns you to enlighten your understanding, to search after truth, to inform yourself of your duties; 186 superstition enjoins you not to examine anything, to remain in ignorance, to fear truth; 187 it persuades you there are no relations so important to your interest, as those which subsist between yourself and systems which you can never understand.

188 Nature tells the being who is in love with your welfare, to moderate your passions, to resist them when they are found destructive to yourself, to counteract them by substantive motives collected from experience; 189 superstition desires a sensible being to have no passions, to be an insensible mass, or else to combat your propensities by motives borrowed from the imagination, which are as variable as itself. 190 Nature exhorts human to be sociable, to love your fellow creatures, to be just, peaceable, indulgent, benevolent, to permit your associates to freely enjoy their opinions; 191

superstition admonishes you to fly society, to detach yourself from your fellow mortals, to hate them when their imagination does not procure them dreams conformable to your own; 192 to break through the most sacred bonds, to maintain your own opinions, or to frustrate those of your neighbour; to torment, to persecute, to massacre, those who will not be mad after your own peculiar manner. 193 Nature exacts that person in society should cherish glory, labour to render the self estimable, endeavour to establish an imperishable name, to be active, courageous, industrious; 194 superstition tells you to be abject, pusillanimous, to live in obscurity, to occupy yourself with ceremonies; it says to you, be useless to thyself, and do nothing for others.

195 Nature proposes to the citizen, for your model, people endued with honest, noble, energetic souls, who have usefully served their fellow citizens; 196 superstition recommends to your imitation mean, cringing sycophants; extols pious enthusiasts, frantic penitents, zealous fanatics, who for the most ridiculous opinions have disturbed the tranquillity of empires. 197 Nature urges the husband to be tender, to attach the self to the company of your mate, to cherish the wife in your bosom; 198 superstition makes a crime of your susceptibility, frequently obliges you to look upon the conjugal bonds as a state of pollution, as the offspring of imperfection. 199 Nature calls to the father to nurture your children, to cherish their affection, to make them useful members of society; 200 superstition advises you to rear them in fear of its systems, to hoodwink them, to make them superstitious, which renders them incapable of actually serving society, but extremely well calculated to disturb its repose. 201 Nature cries out to children to honour their parents, to listen to their admonitions, to be the support of their old age; 202 superstition says, prefer the oracles; in support of the systems of which you are an admitted member, trample father and mother under your feet.

NATURE

203 Nature holds out to the philosopher that you should occupy yourself with useful objects, consecrate your cares to your country, make advantageous discoveries, suitable to perfect the condition of humankind; 204 superstition saith, occupy thyself with useless reveries; employ thy time in endless dispute; scatter about with a lavish hand the seeds of discord, calculated to induce the carnage of thy fellows; obstinately maintain opinions which thou thyself canst never understand. 205 Nature points out to the perverse person, that you should blush for your vices, that you should feel sorrow for your disgraceful propensities, that you should be ashamed of crime; 206 it shows you, that your most secret irregularities will necessarily have an influence over his your own felicity; 207 superstition crieth to the most corrupt people, to the most flagitious mortals, "do not irritate the gods, whom thou knowest not; 208 but if, peradventure, against their express command, thou dost deliver thyself up to crime, remember that their mercy is infinite, that their compassion endureth for ever, that therefore they may be easily appeased; 209 thou hast nothing more to do than to go into their temples, prostrate thyself before their altars, humiliate thyself at the feet of their ministers; expiate thy transgressions by largesses, by sacrifices, by offerings, by ceremonies, and by prayer; 210 these things done with a willing spirit, and a contrite heart, will pacify thine own conscience, and cleanse thee in the eyes of heaven."

211 The rights of the citizen, or the person in society, are not less injured by superstition, which is always in contradiction with sound politics. 212 Nature says distinctly to human, "thou art free; no power on earth can justly deprive thee of thy rights, without thine own consent; 213 and even then, thou canst not legitimately make thyself a slave to thy like." 214 Superstition tells you that you are a slave, condemned to groan all your life under the iron rod of the representatives of its system. 215 Nature commands human to love the

country which gave you birth, to serve it faithfully, to blend your interests with it, to unite against all those who shall attempt to injure it; 216 superstition generally orders you to obey without murmur the tyrants who oppress it, to serve them against its best interests, to merit their favours by contributing to enslave their fellow citizens to their ungovernable caprices: 217 notwithstanding these general orders, if the sovereign be not sufficiently devoted to the priest, superstition quickly changes its language, it then calls upon subjects to become rebels; 218 it makes it a duty in them to resist their masters; it cries out to them, "it is better to obey the gods than humans."

219 Nature acquaints princes that they are humans: that it is not by their capricious whims that they can decide what is just; that it is not their wayward humours that can mark what is unjust; that the public will maketh the law. 220 Superstition often insinuates to them that they are gods, to whom nothing in this world ought to offer resistance; 221 sometimes, indeed, it transforms them into tyrants, whom enraged heaven is desirous should be immolated to its wrath. 222 Superstition corrupts princes; these corrupt the law, which, like themselves, becomes unjust; from thence institutions are perverted; 223 education only forms people who are worthless, blinded with prejudice, smitten with vain objects, enamoured of wealth, devoted to pleasures, which they must obtain by iniquitous means: 224 thus Nature, mistaken, is disdained; virtue is only a shadow quickly sacrificed to the slightest interest, 225 while superstition, far from remedying these evils to which it has given birth, does nothing more than render them still more inveterate; or else engenders sterile regrets which it presently effaces: 226 thus, by its operation, human is obliged to yield to the force of habit, to the general example, to the stream of those propensities, to those causes of confusion, 227 which conspire to hurry all your species, who are not willing to renounce their own

welfare, on to the commission of crime.

228 Here is the mode by which superstition, united with politics, exert their efforts to pervert, abuse, and poison the heart of human; 229 the generality of human institutions appear to have only for their object to abase the human character, to render it more flagitiously wicked. 230 Do not then let us be at all astonished if morality is almost everywhere a barren speculation, from which everyone is obliged to deviate in practice, if you will not risk the rendering yourself unhappy. 231 People can only have sound morals, when, renouncing your prejudices, you consults your nature; 232 but the continued impulse which your soul is every moment receiving, on the part of more powerful motives, quickly compels you to forget those ethical rules which Nature points out to you. 233 You are continually floating between vice and virtue; we behold you unceasingly in contradiction with yourself; 234 if, sometimes, you justly appreciates the value of an honest, upright conduct, experience very soon shows you, that this cannot lead you to anything, which you have been taught to desire, 235 on the contrary, that it may be an invincible obstacle to the happiness which your heart never ceases for an instant to search after.

236 In corrupt societies it is necessary to become corrupt, in order to become happy. 237 Citizens, led astray at the same time both by their spiritual and temporal guides, neither knew reason nor virtue. 238 The slaves both of their superstitious systems, and of people like themselves, they had all the vices attached to slavery; kept in a perpetual state of infancy, they had neither knowledge nor principles; 239 those who preached virtue to them, knew nothing of it themselves, and could not undeceive them with respect to those baubles in which

they had learned to make their happiness consist. 240 In vain they cried out to them to stifle those passions which everything conspired to unloose: 241 in vain they made the thunder of the gods roll to intimidate people whose tumultuous passions rendered them deaf. 242 It was soon discovered that the gods of the heavens were much less feared than those of the earth; that the favour of the latter procured a much more substantive welfare than the promises of the former; 243 that the riches of this world were more tangible than the treasures reserved for favourites in the next; 244 that it was much more advantageous for people to conform themselves to the views of visible powers than to those of powers who were not within the compass of their visual faculties.

245 Thus society, corrupted by its priests, guided by their caprice, could only bring forth a corrupt offspring. 246 It gave birth to avaricious, ambitious, jealous, dissolute citizens, who never saw anything happy but crime; who beheld meanness rewarded; incapacity honoured; wealth adored; debauchery held in esteem; 247 who almost everywhere found talents discouraged; virtue neglected; truth proscribed; elevation of soul crushed; justice trodden under foot; moderation languishing in misery; liberality of mind obligated to groan under the ponderous bulk of haughty injustice.

248 In the midst of this disorder, in this confusion of ideas, the precepts of morality could only be vague declamations, incapable of convincing any one.

249 What barrier could superstition, with its imaginary motives, oppose to the general corruption? When it spake reason, it could not be heard; 250 its gods themselves were not sufficiently powerful to resist the torrent; its menaces failed of effect, on those hearts which everything hurried along to crime; 251 its distant promises could not counterbalance

present advantages; its expiations, always ready to cleanse mortals from their sins, emboldened them to persevere in their criminal pursuits; 252 its frivolous ceremonies calmed their consciences; its zeal, its disputes, its caprices, only multiplied the evils, with which society found itself afflicted; only gave them an inveteracy that rendered them more widely mischievous; 253 in short, in the most vitiated nations there was a multitude of devotees, and but very few honest people. 254 Great and small listened to the doctrines of superstition, when they appeared favourable to their dominant passions; when they were desirous to counteract them, they listened no longer. 255 Whenever superstition was conformable to morality, it appeared incommodious, it was only followed when it either combated ethics or destroyed them. 256 The despot themselves found it marvellous, when they assured you they was a god upon earth; that their subjects were born to adore them alone, to administer to their phantasms. 257 They neglected it when they told you to be just; from thence they saw it was in contradiction with itself, that it was useless to preach equity to a deified mortal; 258 besides, they was assured the gods would pardon everything, as soon as they should consent to recur to their priests, always ready to reconcile them; 259 the most wicked of their subjects reckoned in the same manner upon their divine assistance: 260 thus superstition, far from restraining vice, assured its impunity; its menaces could not destroy the effects which its unworthy flattery had produced in princes; 261 these same menaces could not annihilate the hope which its expiations had furnished to all. 262 Sovereigns, either inflated with pride, or always confident of washing out their crimes by timely sacrifices, no longer actually feared their gods; 263 become gods themselves, they believed they were permitted anything against poor pitiful mortals, whom they no longer considered under any other light than as playthings destined for their earthly amusement.

NATURE

264 If the nature of human was consulted in own politics which supernatural ideas have so woefully depraved, it would completely rectify those false notions that are entertained equally by sovereigns and by subjects; 265 it would contribute more amply than all the superstitions existing, to render society happy, powerful, and flourishing under rational authority. 266 Nature would teach human, it is for the purpose of enjoying a greater portion of happiness, that mortals live together in society; 267 that it is its own preservation, its own immediate felicity, that society should have for its determinate, unchangeable object: 268 that without equity, a nation only resembles a congregation of enemies; that your most cruel foe, is the person who deceives you in order that you may be enslaved; 269 that the scourges most to be feared, are those priests who corrupt their chiefs, who, in the name of the gods assure them of impunity for their crimes: 270 She would prove to you that association is a misfortune under unjust, negligent, destructive governments.

271 This Nature, interrogated by princes, would teach them they are humans and not gods; that their power is only derived from the consent of other humans; 272 that they themselves are citizens, charged by other citizens, with the care of watching over the safety of the whole; 273 that the law ought to be only the expression of the public will; that it is never permitted them to counteract Nature, or to thwart the invariable end of society.

274 This Nature would make monarchs feel, that to be truly great, to be decidedly powerful, they ought to command elevated, virtuous souls; not minds degraded by despotism, vitiated by superstition.

275 This Nature would teach sovereigns, that in order to be cherished by their subjects, they ought to afford them succour; 276 to cause them to enjoy those benefits which their wants render imperative, that they should at all times maintain them, inviolably, in the possession of

their rights, of which they are the appointed defenders-- of which they are the constituted guardians.

277 This Nature would prove to all those princes who should deign to consult Her, that it is only by good actions, by kindness, they can either merit the love, or secure the attachment of the people; 278 that oppression does nothing more than raise up enemies against them; that violence only makes their power unsteady; that force, however brutally used, cannot confer on them any legitimate right; 279 that beings essentially in love with happiness, must sooner or later finish by revolting against an authority that establishes itself by injustice; that only makes itself felt by the outrage it commits: 280 this is the manner in which Nature, the sovereign of all beings, in whose system all are equal, would speak to one of these superb monarchs, whom flattery has deified:--

281 "Untoward, headstrong child! Pygmy, so proud of commanding pygmies! Have they then assured thee that thou art a god? 282 Have they flattered thee that thou art something supernatural? Know there is nothing superior to myself. 283 Contemplate thine own insignificance, acknowledge thine impotence against the slightest of my blows. 284 I can break thy sceptre; I can take away thine existence; I can level thy throne with the dust; I can scatter thy people; I can destroy even the earth which thou inhabitest; and yet thou hast the folly to believe thou art a god. 285 Be then, again, thyself; honestly avow that thou art a human, formed to submit to my laws equally with the meanest of thy subjects. 286 Learn then, and never let it escape thy memory, that thou art the human of thy people; the minister of thy nation; the interpreter of its laws; the executor of its will; 287 the fellow-citizen of those whom thou hast the right of commanding, only because they consent to obey thee, in view of that well being which thou promisest to procure for them. 288 Reign, then, on these conditions; fulfill thy sacred engagements. Be benevolent: above all, equitable.

289 If thou art willing to have thy power assured to thee, never abuse it; let it be circumscribed by the immovable limits of eternal justice. 290 Be the father of thy people, and they will cherish thee as thy children. 291 But, if unmindful of thy duties, thou neglectest them; if negligent of thine own interest, thou separatest them from those of thy great family, 292 if thou refusest to thy subjects that happiness which thou owest them; if, heedless of thy own security, thou armest thyself against them; 293 thou shall be like all tyrants, the slave to gloomy care, the bondman of alarm, the vassal of cruel suspicion: thou wilt become the victim to thine own folly.

294 Thy people, reduced to despair, shorn of their felicity, will no longer acknowledge thy divine rights. 295 In vain, then, thou wouldst sue for aid to that superstition which hath deified thee; it can avail nothing with thy people, whom sharp misery had rendered deaf; 296 heaven will abandon thee to the fury of those enemies to which thy frenzy shall have given birth. 297 Superstitious systems can effect nothing against my irrevocable decrees, which will that human shall ever irritate the self against the cause of own sorrows." 298 In short, everything would make known to rational princes, that they have no occasion for superstition to be faithfully obeyed on earth; 299 that all the powers contained in these systems will not sustain them when they shall act the tyrant; 300 that their true friends are those who undeceive the people in their delusions; that their real enemies are those who intoxicate them with flattery-- who harden them in crime-- who make the road to heaven too easy for them-- 301 who feed them with fanciful, chimerical doctrines, calculated to make them swerve from those cares, to divert them from those sentiments, which they justly owe to their nations. 302 It is then, I repeat it, only by re-conducting human to Nature, that we can procure you distinct notions, evident opinions, certain knowledge; 303 it is only by showing you your true relations with your fellows, that we

can place you on the road to happiness.

304 The human mind, blinded by theology, has scarcely advanced a single step. 305 Human's superstitious systems have rendered you sceptical on the most demonstrable truths. 306 Superstition, while it pervaded everything, while it had an universal influence, served to corrupt the whole: 307 philosophy, dragged in its train, although it swelled its triumphant procession, was no longer anything but an imaginary science: 308 it quitted the real world to plunge into the sinuosities of the ideal, inconceivable labyrinths of metaphysics; 309 it neglected Nature, who spontaneously opened Her book to its examination, to occupy itself with systems filled with spirits, with invisible powers, which only served to render all questions more obscure; 310 which, the more they were probed, the more inexplicable they became; which took delight in promulgating that which no one was competent to understand. 311 In all difficulties it introduced the Divinity; from thence things only became more and more perplexed, until nothing could be explained.

312 Theological notions appear only to have been invented to put human's reason to flight; to confound your judgment; to deceive your mind; to overturn your clearest ideas in every science. 313 In the hands of the theologian, logic, or the art of reasoning, was nothing more than an unintelligible jargon, calculated to support sophism, to countenance falsehood, to attempt to prove the most palpable contradictions. 314 Morality, as we have seen, became wavering and uncertain, because it was founded on ideal systems, never in harmony with themselves, which, on the contrary, were continually contradicting their own most positive assertions. 315 Politics, as we have elsewhere said, were cruelly perverted by the fallacious ideas given to sovereigns of their actual rights. 316 Jurisprudence was determinately submitted to the caprices of superstition, which shackled labour, chained down human industry, controlled activity,

and fettered the commerce of nations. 317 Everything, in short, was sacrificed to the immediate interests of these theologians: 318 in the place of every rational science, they taught nothing but an obscure, quarrelsome metaphysics, which but too often caused the blood of those unhappy people to flow copiously who were incapable of understanding its hallucinations.

319 Born an enemy to experience, theology, that supernatural science, was an invincible obstacle to the progress of the natural sciences, as it almost always threw itself in their way. 320 It was not permitted to experimental philosophy, to natural history, to anatomy, to see anything but through the jaundiced eye of superstition. 321 The most evident facts were rejected with disdain, proscribed with horror, whenever they could not be made to quadrate with the idle hypotheses of superstition. 322 Virgil, the Bishop of Saltzburg, was condemned by the church, for having dared to maintain the existence of the antipodes; 323 Gallileo suffered the most cruel persecutions, for asserting that the sun did not make its revolution round the earth. 324 Descartes was obliged to die in a foreign land. 325 Priests, indeed, have a right to be the enemies to the sciences; the progress of reason must, sooner or later, annihilate superstitious ideas. 326 Nothing that is founded upon Nature, that is bottomed upon truth, can ever be lost; while the systems of imaginations, the creeds of imposture, must be overturned. 327 Theology unceasingly opposed itself to the happiness of nations-- to the progress of the human mind-- to useful researches-- to the freedom of thought; it kept human in ignorance; all your steps being guided by it, you was no more than a tissue of errors.

328 Indeed, is it resolving a question in natural philosophy, to say that an effect which excites our surprise, that an unusual phenomenon, that a volcano, a deluge, a hurricane, a comet, are either signs of divine wrath, or works contrary to the laws of Nature? 329 In persuading nations, as it has done, that the calamities, whether physical or moral, which

they experience, are the effects of the divine anger, or chastisements which His power inflicts on them, has it not, in fact, prevented them from seeking after remedies for these evils? 330 Would it not have been more useful to have studied the nature of things, to have sought in Nature Herself, or in human industry, for succours against those sorrows with which mortals are afflicted, 331 than to attribute the evil which human experiences to an unknown power, against those will it cannot be supposed there exists any relief?

332 The study of Nature, the search after truth, elevates the soul, expands the genius, is calculated to render human active, to make you courageous. 333 Theological notions appear to have been made to debase you, to contract your mind, to plunge you into despondence. 334 In the place of attributing to the divine vengeance those wars, those famines, those sterilities, those contagions, that multitude of calamities, which desolate the earth; 335 would it not have been more useful, more consistent with truth, to have shown human that these evils were to be ascribed to your own folly, 336 or rather to the unruly passions, to the want of energy, to the tyranny of some princes, who sacrifice nations to their frightful delirium? 337 The irrational people, instead of amusing themselves with expiations for their pretended crimes, seeking to render themselves acceptable to imaginary powers; 338 should they not rather have sought in a more healthy administration, the true means of avoiding those scourges, to which they were the victims? 339 Natural evils demand natural remedies: ought not experience then long since to have convinced mortals of the inefficacy of supernatural remedies, 340 of expiatory sacrifices, of fastings, of processions. which almost all the people of the earth have vainly opposed to the disasters which they experienced?

341 Let us then conclude, that theology with its notions, far from being useful to the human species, is the true source of all those sorrows which afflict the earth of all those

errors by which human is blinded; 342 of those prejudices which benumb humankind; of that ignorance which renders you credulous; of those vices which torment you; of those governments which oppress you. 343 Let us be fully persuaded that those theological, supernatural ideas, with which human is inspired from own infancy, are the actual causes of your habitual folly; are the springs of your superstitious quarrels; of your sacred dissensions; of your inhuman persecutions. 344 Let us, at length, acknowledge, that they are these fatal ideas which have obscured morality; corrupted polities; retarded the progress of the sciences; annihilated happiness; banished peace from the bosom of humankind, 345 Then let it be no longer dissimulated, that all those calamities, for which human turns own eyes towards heaven, bathed in tears, have their spring in the imaginary systems you have adopted: 346 let you, therefore, cease to expect relief from them; let you seek in Nature, let you search in your own energies, those resources, which superstition, deaf to your cries, will never procure for you. 347 Let you consult the legitimate desires of your heart, and you will find that which you oweth to yourself, also that which you oweth to others; 348 let you examine your own essence, let you dive into the aim of society, from thence you will no longer be a slave; 349 let you consult experience, you will find truth, and you will discover, that error can never possible render you happy.

HUMAN CAN FORM NO CONCLUSION FROM THE IDEAS WHICH ARE OFFERED THEM OF THE DIVINITY

Paul Henri Thiery (Baron D'Holbach)

53 It has been already stated, that ideas to be useful, must be founded upon truth; that experience must at all times demonstrate their justice: 2 if, therefore, as we have proved, the erroneous ideas which human has in almost all ages formed to the self of the Divinity, far from being of

utility, 3 are prejudicial to morality, to politics, to the happiness of society, to the welfare of the individuals who compose it, in short, to the progress of the human understanding; 4 reason, and our interest, ought to make us feel the necessity of banishing from our mind these illusive, futile opinions, which can never do more than confound it--which can only disturb the tranquillity of our hearts. 5 In vain should we flatter ourselves with arriving at the correction of theological notions; erroneous in their principles, they are not susceptible of reform. 6 Under whatever shape an error presents itself, as soon as human shall attach an undue importance to it, it will, sooner or later, finish by producing consequences dangerous in proportion to their extent. 7 Besides, the inutility of those researches, which in all ages have been made after the true nature of the Divinity, the notions that have hitherto been entertained, 8 have done little more than throw it into greater obscurity, even to those who have most profoundly meditated on the subject; 9 then, ought not this very in utility to convince us that this subject is not within the reach of our capacity 10 that this being will not be better known to us, or by our descendants, than it hath been to our ancestors, either the most savage or the most ignorant?

11 The object, which of all others human has at all times reasoned upon the most, written upon the most, nevertheless remains the least known; 12 far from progressing in your research, time, with the aid of theological ideas, has only rendered it more impossible to be conceived. 13 If the Divinity be such as dreaming theology depicts, you must yourself be a Divinity who is competent to form an idea of Him. 14 We know little of human, we hardly know ourselves, or our own faculties, yet we are disposed to reason upon a being inaccessible to our senses. 15 Let us, then, travel in peace over the line described for us by Nature, without having a wish to diverge from it, to hunt after vague systems; 16 let us occupy ourselves with our

true happiness; let us profit of the benefits spread before us; let us labour to multiply them, by diminishing the number of our errors; 17 let us quietly submit to those evils we cannot avoid, and not augment them by filling our mind with prejudices calculated to lead us astray. 18 When we shall give it serious reflection, everything will clearly prove that the pretended science of theology is, in truth, nothing but presumptuous ignorance, masked under pompous, unintelligible words. 19 In short, let us terminate unfruitful researches; be content at least to acknowledge our invincible ignorance; 20 it will clearly be more substantively advantageous, than an arrogant science, which has hitherto done little more than sow discord on the earth-- affliction in the heart of human.

21 In supposing a sovereign intelligence who governs the world; in supposing a Divinity who exacts from His creatures that they should have a knowledge of Him, 22 that they should understand His attributes, His wisdom, His power; who is desirous they should render him homage; 23 it must be allowed, that no human on earth in this respect completely fulfills the views of providence. 24 Indeed, nothing is more demonstrable than the impossibility in which the theologians find themselves, to form to their mind any idea whatever of the Divinity.

25 Procopius, the first bishop of the Goths, says in the most solemn manner: "I esteem it a very foolish temerity to be disposed to penetrate into the knowledge of the nature of God;" 26 and further on he acknowledges, "that he has nothing more to say of Him, except that He is perfectly good. 27 One who knoweth more, whether you be ecclesiastic or layman, has only to tell it."

28 The weakness, the obscurity of the proofs offered, of the systems attributed to Him, the manifest contradictions into which they fall, 29 the sophism, the begging of the question, which are employed, evidently prove they are themselves in the greatest incertitude upon the

nature of that being with whom it is their profession to occupy their thoughts: 30 even the author of A New View of Society acknowledges, "that up to this moment it is, not possible yet to say which is right or which is wrong: 31 that had any one of the various opposing systems which until this day have governed the world, and disunited human from human, been true, without any mixture of error; 32 that system, very speedily after its public promulgation, would have pervaded society, and compelled all people to have acknowledged its truth." 33 But granting that they have a knowledge of this being, that His essence, His attributes, His systems, were so fully demonstrated to them, as no longer to leave any doubt in their mind, 34 do the rest of the human race enjoy the same advantages? Are they, in fact, in a condition to be charged with this knowledge? 35 Ingenuously, how many people are to be found in the world, who have the leisure, the capacity, the penetration, necessary to understand what is meant to be designated under the name of an immaterial being-- 36 of a pure spirit, who moveth matter without being Himself matter; 37 who is the motive of all the powers of Nature, without being contained in Nature-- without being able to touch it? 38 Are there, in the most religious societies, many people who are competent to follow their spiritual guides, in the subtle proofs which they adduce in evidence of their creeds, upon which they bottom their systems of theology?

39 Without question very few people are capable of profound, connected meditation; the exercise of intense thought is, for the greater number, a species of labour as painful as it is unusual. 40 The people, obliged to toil hard, in order to obtain subsistence, are commonly incapable of reflection; 41 nobles, people of the world, women, young people, occupied with their own immediate affairs, taken up with gratifying their passions, employed in procuring themselves pleasure, as rarely think deeply as the uninformed. 42 There are not, perhaps, two people in an hundred thousand, who have

seriously asked themselves the question, What it is they understand by the word God? 43 Whilst it is extremely rare to find people to whom the nature of God is a problem. 44 Nevertheless, as we have said, conviction supposes that evidence alone has banished doubt from the mind. 45 Where, then, are the web who are convinced of the rectitude of these systems? 46 Who are those in whom we shall find the complete certitude of these truths, so important to all? 47 Who are the people, who have given themselves an accurate account of the ideas they have formed upon the Divinity, upon His attributes, upon His essence?

48 Alas! throughout the whole world, are only to be seen some speculators, who, by dint of occupying themselves with the idea, have, with great fatuity, believed they have discovered something decisive in the confused, unconnected wanderings of their own imagination; 49 they have, in consequence, endeavoured to form a whole, which, chimerical as it is, they have accustomed themselves to consider as actually existing: 50 by force of musing upon it, they have sometimes persuaded themselves they, saw it distinctly; 51 these have not infrequently succeeded in making others believe, their reveries, although they may not have mused upon it quite so much as themselves.

52 It is seldom more than hearsay, that the mass of the people adopt either the systems of their fathers, or of their priests: 53 authority, confidence, submission, habit, take place of conviction-- supersede proof; 54 they prostrate themselves before idols, lend themselves to different creeds, because their ancestors have taught them to fall down, and worship; 55 but never do they inquire wherefore they bend the knee: it is only because, in times far distant, their legislators, their guides, have imposed it upon them as a duty; 56 these have said, "adore and believe those gods, whom ye cannot comprehend; yield yourselves in this instance to our profound wisdom; we know

more than ye do respecting the Divinity." 57 But wherefore, it might be inquired, should I take this system upon your authority? 58 It is, they will reply, because the gods will have it thus; because they will punish you, if you dare to resist. But are not these gods the thing in question? 59 Nevertheless, human has always been satisfied with this circle of errors; the idleness of your mind made you find it most easy to yield to the judgment of others.

60 All superstitions are uniformly founded upon error, established by authority; equally forbid examination; are equally indisposed to permit that human should reason upon them; 61 it is power that wills you should unconditionally accredit them: 62 they are rested solely upon the influence of some few people, who pretend to a knowledge of things, which they admit are incomprehensible for all their species; 63 who, at the same time, affirm they are sent as missionaries to announce them to the inhabitants of the earth: 64 these inconceivable systems, formed in the brain of some enthusiastic people, have most unquestionably occasion for people to expound them to their fellows. 65 Human is generally credulous as a child upon those objects which relate to superstition; you are told you must believe them; 66 as you generally understands nothing of the matter, you imagines you runs no risk in joining sentiments with your priest, whom you supposes has been competent to discover what you yourself is not able to comprehend. 67 The most rational people argue thus: "What shall I do? What interest can so many people have to deceive?" 68 But, seriously, does this prove that they do not deceive? They may do it from two motives: either because they are themselves deceived, or because they have a great interest in deceiving.

69 By the confession of the theologians themselves, human is, for the greater part, without religion: you have only superstition. 70 Superstition, according to them, "is a worship of the Divinity, either badly

understood or irrational," or else, "worship rendered to a false Divinity." 71 But where are the people or the clergy who will allow, either that their Divinity is false, or their worship irrational? 72 How shall it be decided who is right, or who is wrong? 73 It is evident that in this affair great numbers must be wrong. 74 Indeed, Buddaeus, in his Treatise on Atheism, tells us, "in order that a religion may be true, not only the object of the worship must be true, but we must also have a just idea of it. 75 You, then, who adoreth God without knowing Him, adoreth Him in a perverse and corrupt manner, and is generally guilty of superstition." 76 This granted, would it not be fair to demand of the theologians, if they themselves can boast of having a just idea or real knowledge of the Divinity? 77 Admit for a moment they have, would it not then be evident, that it is for the priest, for the inspired, for the metaphysician, that this idea, which is said to be so necessary for the whole human race, is exclusively reserved?

78 If we examine, however, we shall not find any harmony among the theological notions of these various inspired people, or of that hierarchy which is scattered over the earth: 79 even those who make a profession of the same system, are not in unison upon the leading points. 80 Are they ever contented with the proofs offered by their colleagues? Do they unanimously subscribe to each other's ideas? 81 Are they agreed upon the conduct to be adopted; upon the manner of explaining their texts; upon the interpretation of the various oracles? 82 Does there exist one country upon the whole earth, where the science of theology is actually perfectioned?-- 83 where the ideas of the Divinity are rendered so clear, as not to admit of cavil? 84 Has this science obtained any of that steadiness, any of that consistency, any of that uniformity, which is found attached to other branches of human knowledge; even to the most futile arts, or to those trades which are most despised?

85 Has the multitude of subtle distinctions, with which theology in some countries is filled throughout; have the words spirit, immateriality, incorporeity, predestination, grace, with other ingenious inventions, imagined by sublime thinkers, 86 who during so many ages have succeeded each other, actually had any other effect than to perplex things; to render the whole obscure; decidedly unintelligible? 87 Alas! do, they not offer practical demonstration, that the science held forth as the most necessary to human, has not, hitherto, been able to acquire the least degree of stability; 88 has remained in the most determined state of indecision; has entirely failed in obtaining solidity? 89 For thousands of years the most idle dreamers have been relieving each other, meditating on systems, diving into concealed ways, inventing hypothesis suitable to develop this important enigma. 90 Their slender success has not at all discouraged theological vanity; the priests have always spoken of it as of a thing with which they were most intimately acquainted; 91 they have disputed with all the pertinancy of demonstrated argument; they have destroyed each other with the most savage barbarity; 92 yet, notwithstanding, to this moment, this sublime science remains entirely unauthenticated; almost unexamined.

93 Indeed, if things were coolly contemplated, it would be obvious that these theories are not formed for the generality of humankind, who for the most part are utterly incompetent to comprehend the aerial subtilities upon which they rest. 94 Who is the person, that understandeth any thing of the fundamental principles of these systems? 95 Whose capacity embraces spirituality, immateriality, incorporeity, or the mysteries of which you are every day informed? 96 Are there many people who can boast of

perfectly understanding the state of the question, in those theological disputations, which have frequently had the potency to disturb the repose of humankind? 97 Nevertheless, even women believe themselves obliged to take part in the quarrels excited by these idle speculators, who are of less actual utility, to society, than the meanest artisan.

98 Human would, perhaps, have been too happy, if confining the self to those visible objects which interest you, you had employed half that energy which you have wasted in researches after incomprehensible systems, upon perfectioning the real sciences; 99 in giving consistency to your laws; in establishing your morals upon solid foundations; in spreading a wholesome education among your fellows. you would, unquestionably, have been much wiser, more fortunate, 100 if you had agreed to let your idle, unemployed guides quarrel among themselves unheeded; if you had permitted them to fathom those depths calculated to astound the mind, to amaze the intellect, without inter-meddling with their irrational disputes. 101 But it is the essence of ignorance, to attach great importance to everything which it doth not understand. 102 Human vanity makes the mind bear up against difficulties. 103 The more an object eludes our inquiry, the more efforts we make to compass it; because from thence our pride is spurred on, our curiosity is set afloat, our passions are irritated, and it assumes the character of being highly interesting to us. 104 On the other hand, the more continued, the more laborious our researches have been, the more importance we attach to either our real or our pretended discoveries; the more we are desirous not to have wasted our time; 105 besides, we are always ready warmly to defend the soundness of our own judgment. 106 Do not let us then be surprised at the interest that

ignorant people have at all times taken in the discoveries of their priests; nor at the obstinate pertinacity which they have ever manifested in their disputes. 107 Indeed, in combating for your own peculiar system, each only fought for the interests of own vanity, which of all human passions is the most quickly alarmed, the most calculated to lead human on to the commission of great follies.

108 Theology is truly the vessel of the Danaides. By dint of contradictory qualities, by means of bold assertions, it has so shackled its own systems as to render it impossible they should act. 109 Indeed, when even we should suppose the existence of these theological systems, the reality of codes so discordant with each other and with themselves, we can conclude nothing from them to authourise the conduct, or sanction the mode of worship which they prescribe. 110 If their gods are infinitely good, wherefore should we dread them? 111 If they are infinitely wise, what reason have we to disturb ourselves with our condition? 112 If they are omniscient, wherefore inform them of our wants, why fatigue them with our requests? 113 If they are omnipresent, of what use can it be to erect temples to them? 114 If they are lords of all, why make sacrifices to them; why bring them offerings of what already belongs to them? 115 If they are just, upon what foundation believe that they will punish those creatures whom they have filled with imbecility? 116 If their grace works everything in human, what reason can there be why you should be rewarded? 117 If they are omnipotent, how can they be offended; how can we resist them? 118 If they are rational, how can they enrage themselves against blind mortals, to whom they have left the liberty of acting irrationally? 119 If they are immutable, by what right shall we pretend to make them change

their decrees? 120 If they are inconceivable, wherefore should we occupy ourselves with them? 121 If the knowledge of these systems be the most necessary thing, wherefore are they not more evident, more consistent, more manifest?

122 This granted, you who can undeceive yourself on the afflicting notions of these theories, hath this advantage over the credulous, trembling, superstitious mortal-- 123 that you establishes in your heart a momentary tranquillity, which, at least, rendereth you happy in this life. 124 If the study of Nature hath banished from your mind, those chimeras with which the superstitions person is infested, you, at least, enjoys a security of which this sees yourself deprived. 125 In consulting this Nature, your fears are dissipated, your opinions, whether true or false, acquire a steadiness of character; 126 a calm succeeds the storm, which panic terror, the result of wavering notions, excite in the hearts of all people who occupy themselves with these systems. 127 If the human soul, cheered by philosophy, had the boldness to consider things coolly; it would no longer behold the universe submitted to implacable systems, under which human is continually trembling. 128 If you was rational, you would perceive that in committing evil you did not disturb Nature; 129 that you either injureth yourself alone, or injures other beings capable of feeling the effects of your conduct, from thence you would know the line of your duties; 130 you would prefer virtue to vice, for your own permanent repose: 131 you would, for your own satisfaction, for your own felicity in this world, find yourself deeply interested in the practice of moral goodness; 132 in rendering virtue habitual; in making it dear to the feeling of your heart: your own immediate welfare would be concerned in avoiding vice, 133 in detesting crime, during the short season of your abode among intelligent, sensible beings, from whom you expects your happiness.

134 By attaching yourself to these rules, you would live contented with

your own conduct; 135 you would be cherished by those who are capable of feeling the influence of your actions; 136 you would expect without inquietude the term when your existence should have a period; 137 you would have no reason to dread the existence which might follow the one you at present enjoys: 138 you would not fear to be deceived in your reasoning. 139 Guided by demonstration, led gently along by honesty, you would perceive that you could have nothing to dread from a beneficent Divinity, 140 who would not punish you for those involuntary errors which depend upon the organisation, which without your own consent you have received. 141 Such a person so conducting the self, would have nothing to apprehend, whether at the moment of own death, you falls asleep for ever; 142 or whether that sleep is only a prelude to another existence, in which you shall find yourself in the presence of your God. 143 Addressing yourself to the Divinity, you might with confidence say, "O God! Father, who hath rendered thyself invisible to thy child! Inconceivable, hidden Author of all, whom I could not discover! 144 Pardon me, if my limited understanding hath not been able to know thee, in a Nature, where everything hath appeared to me to be necessary! 145 Excuse me, if my sensible heart hath not discerned thine august traits among those numerous systems which superstitious mortals tremblingly adore: 146 if, in that assemblage of irreconcilable qualities, with which the imagination hath clothed thee, I could only see a phantom. 147 How could my coarse eyes perceive thee in Nature, in which all my senses have never been able to bring me acquainted but with material beings, with, perishable forms? 148 Could I, by the aid of these senses, discover thy spiritual essence, of which no one could furnish me any idea? 149 Could my feeble brain, obliged to form its judgments after its own capacity, discern thy plans, measure thy wisdom, conceive thine intelligence, 150 whilst the universe presented to my view a continued

mixture of order and confusion-- of good and evil-- of formation and destruction? 151 Have I been able to render homage to the justice of thy priests, whilst I so frequently beheld crime triumphant, virtue in tears? 152 Could I possibly acknowledge the voice of a being filled with wisdom, in those ambiguous, puerile, contradictory oracles, published in thy name in the different countries of the earth I have quitted? 153 If I have not known thy peculiar existence, it is because I have not known either what thou couldst be, where thou couldst be placed, or the qualities which could be assigned thee. 154 My ignorance is excusable, because it was invincible: my mind could not bend itself under the authority of humans, who acknowledged they were as little enlightened upon thine essence as myself; 155 who were forever disputing among themselves; who were in harmony only in imperiously crying out to me, to sacrifice to them that reason which thou hadst given to me; 156 But, oh God! If thou cherishest thy creatures, I also, like thee, have cherished them; I have endeavoured to render them happy, in the sphere in which I have lived. 157 If thou art the author of reason, I have always listened to it-- have ever endeavoured to follow it; 158 if virtue pleaseth thee, my heart hath always honoured it; I have never willingly outraged it: 159 when my powers have permitted me, I have myself practised it; I was an affectionate spouse, a tender partner, a sincere friend, a faithful subject, a zealous citizen; 160 I have held out consolation to the afflicted; and if the foibles of my nature have been either injurious to myself or incommodious to others, I have not at least made the unfortunate groan under the weight of my injustice. 161 I have not devoured the substance of the poor-- I have not seen without pity the widow's tears; 162 I have not heard without commiseration the cries of the orphan.

163 If thou didst render human sociable, if thou was disposed that society should subsist, if thou wast desirous the community might be happy, 164 I have been the enemy to all who oppressed you, the decided

foe to all those who deceived you, in order that they might advantage themselves of your misfortunes. 165 "If I have not thought properly of thee, it is because my understanding could not conceive thee; 166 if I have spoken ill of thy systems, it is because my heart, partaking too much of human nature, revolted against the odious portrait under which they depicted thee. 167 My wanderings have been the effect of the temperament which thou hast given me; 168 of the circumstances in which, without my consent, thou hast placed me; of those ideas, which in despite of me, have entered into my mind. 169 As thou art good, as thou art just,-- as we are assured thou art-- thou wilt not punish me for the wanderings of mine imagination; 170 for faults caused by my passions, which are the necessary consequence of the organisation which I have received from thee. 171 Thus I cannot doubt thy justice, I cannot dread the condition which thou preparest for me. 172 Thy goodness cannot have permitted that I should incur punishment for inevitable errors. 173 Thou wouldst rather prevent my being born, than have called me into the rank of intelligent beings, there to enjoy the fatal liberty of rendering myself eternally unhappy."

174 It is thus that a disciple of Nature, who, transported all at once into the regions of space, should find the self in the presence of own God, 175 would be able to speak, although you should not have been in a condition to lend yourself to all the abstract systems of theology which appear to have been invented for no other purpose than to overturn in your mind all natural ideas. 176 This illusory science seems bent on forming its systems in a manner the most contradictory to human reason; notwithstanding we are obliged to judge in this world according to its dictates; 177 if, however, in the succeeding world, there is nothing conformable to this, what can be of more inutility, than to think of it or reason upon it? 178 Besides, wherefore should we leave it to the judgment of

people, who are, themselves, only enabled to act after our manner? 179 Without a very marked derangement of our organs, our sentiments hardly ever vary upon those objects which either our senses experience, or which reason has clearly demonstrated.

180 In whatever circumstances we are found, we have no doubt either upon the whiteness of snow, the light of day, or the utility of virtue. 181 It is not so with those objects which depend solely upon our imagination--which are not proved to us by the constant evidence of our senses; we judge of them variously, according to the dispositions in which we find ourselves. 182 These dispositions fluctuate by reason of the involuntary impulse which our organs every instant receive, on the part of an infinity of causes, either exterior to ourselves, or else contained within our own frame. 183 These organs are, without our knowledge, perpetually modified, either relaxed or braced by the density, more or less, of the atmosphere; 184 by heat and by cold; by dryness and by humidity; by health and by sickness; by the heat of the blood; by the abundance of bile; by the state of the nervous system. 185 These various causes have necessarily an influence upon the momentary ideas, upon the instantaneous thoughts, upon the fleeting opinions of human. 186 You are, consequently, obliged to see under a great variety of hues, those objects which your imagination presents to you; without it all times having the capacity to correct them by experience: to compare them by memory. 187 This, without doubt, is the reason why human is continually obliged to view own gods, to contemplate own superstitious systems, under such a diversity of aspects, in different periods of own existence. 188 In the moment, when your fibres find themselves disposed to you tremulous, you

will be cowardly, pusillanimous; you will think of these systems only with fear and trembling. 189 In the moment, when these same fibres shall have more tension, you will possess more firmness, you will then view these systems with greater coolness. 190 The theologian will call your pusillanimity, "inward feeling;" "warning from heaven;" "secret inspiration;" 191 but you who knoweth human, will say that this is nothing more than a mechanical motion, produced by a physical or natural cause.

192 Indeed, it is by a pure physical mechanism, that we can explain all the revolutions that take place in the system, frequently from one minute to another; 193 all the fluctuations in the opinions of humankind; all the variations of your judgment: in consequence of which we sometimes see you reasoning justly, sometimes in the most irrational manner. 194 This is the mode by which, without recurring to grace, to inspirations, to visions, to supernatural notions, we can render ourselves an account of that uncertain, that wavering state 195 into which we sometimes behold people fall, when there is a question respecting their superstition, who are otherwise extremely enlightened. 196 Frequently, in despite of all reasoning, momentary dispositions re-conduct them to the prejudices of their infancy, upon which on other occasions they appear to be entirely undeceived. 197 These changes are very apparent, especially under infirmities, in sickness, or at approach of death. The barometer of the understanding is then frequently obliged to fall.

198 Those chimeras which you despised, or which in a state of health, you set down at their true value, are then realised. 199 You trembles, because your machine is enfeebled; you are irrational because your brain is incapable of fulfilling its functions with

exactitude. 200 It is evident these are the actual causes of those changes which the priests well know how to make use of against what they call incredulity; from which they draw proofs of the reality of their sublimated opinions. 201 Those conversions, or those alterations, which take place, in the ideas of human, have always their origin in some derangement of your machine; brought on either by chagrin or by some other natural or known cause. 202 Submitted to the continual influence of physical causes, our systems invariably follow the variations of the body; 203 we reason well when the body is healthy-- when it is soundly constituted; we reason badly when the corporeal faculties are deranged; 204 from thence our ideas become disconnected, we are no longer equal to the task of associating them with precision; we are incapable of finding principles, or to draw from them just inferences; 205 the brain, in fact, is shaken; we no longer contemplate anything under its actual point of view. 206 It is a person of this kind, who does not see things in frosty weather, under the same traits as when the season is cloudy, or when it is rainy; 207 you does not view them in the same manner in sorrow as in gaiety; when in company as when alone. 208 Good sense suggests to us, that it is when the body is sound, when the mind is undisturbed by any mist, that we can reason with accuracy; 209 this state can furnish us with a general standard, calculated to regulate our judgment; even to rectify our ideas, when unexpected causes shall make them waver.

210 If the opinions even of the same individual, are fluctuating, subject to vacillate, how many changes must they experience in the various beings who compose the human race? 211 If there do not, perhaps, exist two people who see a physical object under the same exact form or colour, what much greater variety must they

not have in their mode of contemplating those things which have existence only in their imagination? 212 What an infinity of combinations, what a multitude of ideas, must not minds essentially different, form to themselves when they endeavour to compose an ideal being, which each moment of their existence must present to them under a different aspect? 213 It would, then, be a most irrational enterprise, to attempt to prescribe to human what you ought to think of superstition, which is entirely under the cognisance of your imagination; 214 for the admeasurement of which, as we have very frequently repeated, mortals will never have any common standard.

215 To oppugn the superstitious opinions of human, is to commence hostilities with your imagination-- to attack your fancy-- to be at war with your organisation-- to enter the lists with your habits, 216 which are of themselves sufficient to identify with your existence, the most absurd, the most unfounded ideas. 217 The more imagination human has, the greater enthusiast you will be in matters of superstition; reason will have the less ability to undeceive you in your chimeras. 218 In proportion as your fancy is powerful, these chimeras themselves will become food necessary to its ardency. 219 In fine, to battle with the superstitious notions of human, is to combat the passions you usually indulges for the marvellous; 220 it is to assail you on that side where you are least vulnerable; to force you in that position where you unites all your strength-- where you keeps the most vigilant guard.

221 In despite of reason, those people who have a lively imagination, are perpetually re-conducted to those chimeras which habit renders dear to them, even when they are found troublesome; although they should prove fatal. 222 Thus a tender soul hath occasion for a God that loveth you; the happy enthusiast needeth a God who rewardeth you; the unfortunate visionary wants a God who taketh part in your sorrows; 223 the melancholy devotee requireth a God who chastiseth you, who

maintaineth you in that trouble which has become necessary to your diseased organisation; 224 the frantic penitent exacteth a God, who imposes upon you an obligation to be inhuman towards yourself; 225 whilst the furious fanatic would believe the self unhappy, if you was deprived of a God who commanded you to make others experience the effect of your inflamed humours, of your unruly passions.

226 You are, without question, a less dangerous enthusiast who feeds yourself with agreeable illusions, than you whose soul is tormented with odious spectres. 227 If a placid, tender soul, does not commit ravages in society, a mind agitated by incommodious passions, cannot fall to become, sooner or later, troublesome to own fellow creatures. 228 The God of a Socrates, or a Fenelon, may be suitable to souls as gentle as theirs; but He cannot be that of a whole nation, in which it is extremely rare people of their temper are found: 229 if honest people only view their gods as fitted with benefits; vicious, restless, inflexible individuals, will give them their own peculiar character, from thence will authourise themselves to indulge, a free course to their passions. 230 Each will view own deities with eyes only open to their own reigning prejudice; 231 the number of those who will paint them as afflicting will always be greater, much more to be feared, than those who shall delineate them under seducing colours: 232 for one mortal that those ideas will render happy, there will be thousands who will be made miserable; 233 they will, sooner or later, become an inexhaustible source of contention; a never failing spring of extravagant folly; 234 they will disturb the mind of the ignorant, over whom impostors will always gain ascendancy-- over whom fanatics will ever have an influence: 235 they will frighten the cowardly, terrify the pusillanimous, whose imbecility will incline them to perfidy, whose weakness will render them cruel; 236 they will cause the most upright to tremble, who, even while practising virtue, will fear incurring the divine displeasure; 237 but they will not

arrest the progress of the wicked, who will easily cast them aside, that they may the more commodiously deliver themselves up to crime; 238 or who will even take advantage of these principles, to justify their transgression.

239 In short, in the hands of tyrants, these systems will only serve to crush the liberty of the people; will be the pretext for violating, with impunity, all equitable rights. 240 In the hands of priests they will become talismans, suitable to intoxicate the mind; calculated to hoodwink the people; competent to subjugate equally the sovereign as the subject; 241 in the hands of the multitude, they will be a two-edged sword, with which they will inflict, at the same moment, the most dreadful wounds on themselves-- the most serious injuries on their associates.

242 On the other hand, these theological systems, as we have seen, being only an heap of contradictions, which represent the Divinity under the most incompatible characters, seem to doubt His wisdom, when they invite mortals to address their prayers to Him, for the gratification of their desires; 243 to pray to Him to grant that which He has not thought it proper to accord to them. 244 Is it not, in other words, to accuse Him with neglecting His creatures? Is it not to ask Him to alter the eternal decrees of His justice; to change the invariable laws which He hath Himself determined? 245 Is it not to say to Him, "O, my God! I acknowledge thy wisdom, thine omniscience, thine infinite goodness; nevertheless, thou forgettest thy servant; thou losest sight of thy creature; 246 thou art ignorant, or thou feignest ignorance, of that which you wanteth: dost thou not see that I suffer from the marvellous arrangement, which thy wise laws have made in the universe? 247 Nature, against thy commands, actually renders my existence painful: change then, I beseech thee, the essence which thy will has given to all beings. 248 Grant that the elements, at this moment, lose in my favour their distinguishing properties; so order it, that heavy bodies shall not fall, that fire shall

not burn, 249 that the brittle frame which I have received at thine hands, shall not suffer those shocks which it every instant experiences. 250 Rectify, I pray thee, for my happiness, the plan which thine infinite prudence hath marked out from all eternity."

251 Such is very nearly the euchology which human adopts; such are the discordant, absurd requests which you continually puts up to the Divinity, whose wisdom you extols; 252 whose intelligence you holds forth to admiration; whose providence you eulogises; whose equity you applauds; whilst you are hardly ever contented with the effects of the divine perfections. 253 Human is not more consequent in those thanksgivings which you believes yourself obliged to offer to the throne of grace. 254 Is it not just, you exclaims, to thank the Divinity for His kindness? 255 Would it not be the height of ingratitude to refuse our homage to the Author of our existence; to withhold our acknowledgments from the Giver of everything that contributes to render it agreeable? 256 But does you not frequently offer up His thanksgivings for actions that overwhelm your neighbour with misery? 257 Does not the husbandman on the hill, return thanks for the rain that irrigates your lands parched with drought, 258 whilst the cultivator of the valley is imploring a cessation of those showers which deluge your fields--that render useless the labour of your hands?

259 Thus each becomes thankful for that which own limited views points out to one as one’s immediate interest, regardless of the general effect produced by those circumstances on the welfare of own fellows. 260 Each believes that it is either a peculiar dispensation of providence in own favour, or a signal of the heavenly wrath directed against the self; 261 whilst the slightest reflection would clearly evince it to be nothing more than the inevitable order of things, which take place without the least regard to your individual comforts. 262 From this it will be obvious, that these systems do not teach their votaries,

practically, to love their neighbour as themselves. 263 But in matters of superstition, mortals never reason; they only follow the impulse of their fears; the direction of their imagination; the force of their temperament; the bent of their own peculiar passions; 264 or those of the guides, who have acquired the right of controlling their understanding. 265 Fear has generally created these systems; terror unceasingly accompanies them; it is impossible to reason while we tremble.

266 We do not, however, flatter ourselves that reason will be capable, all at once, to deliver the human race from those errors with which so many causes united have contributed to poison you. 267 The vainest of all projects would be the expectation of curing, in an instant, those epidemical follies, those hereditary fallacies, rooted during so many ages; 268 continually fed by ignorance; corroborated by custom; borne along by the passions made inveterate by interest; grounded upon the fears, established upon the ever regenerating calamities of nations. 269 The ancient disasters of the earth gave birth to the first systems of theology, new revolutions would equally produce others; even if the old ones should chance to be forgotten. 270 Ignorant, miserable, trembling beings, will always either form to themselves systems, or else adopt those which imposture shall announce-- which fanaticism shall be disposed to give them. 271 It would therefore be useless to propose more than to hold out reason to those who are competent to understand it; 272 to present truth to those who can sustain its lustre; who can with serenity contemplate its refulgent beauty; 273 to undeceive those who shall not be inclined to oppose obstacles to demonstration; to enlighten those who shall not desire pertinaciously to persist in error.

274 Let us, then, infuse courage into those who want power to break with their illusions; 275 let us cheer up the honest person, who is much more alarmed by own fears than the wicked, who, in despite of own opinions, always follows the rule of own passions: 276 let us console the

unfortunate, who groans under a load of prejudices which you have not examined: 277 let us dissipate the incertitude of those whose doubts render them unhappy; who ingenuously seek after truth, but who find in philosophy itself only wavering opinions little calculated to determine their fluctuating minds. 278 Let us banish from the person of genius those chimerical speculations which cause you to waste your time; 279 let us wrest your gloomy superstition from the intimidated mortal, who, duped by your vain fears, becomes useless to society; 280 let us remove from the atrabilarious being those systems that afflict you, that exasperate your mind, that do nothing more than kindle your anger against your incredulous neighbour; 281 let us tear from the fanatic those terrible ideas which arm you with poniards against the happiness of your fellows; 282 let us pluck from tyrants, let us snatch from impostors, those opinions which enable them to terrify, to enslave, and to despoil the human species.

283 In removing from honest people their formidable notions let us not encourage those of the wicked, who are the enemies of society; 284 let us deprive the latter of those illegitimate sources, upon which they reckon to expiate their transgressions; 285 let us substitute actual, present terrors, to those which are distant and uncertain to those which do not arrest the most licentious excesses; 286 let us make the profligate blush at beholding themselves what they really are; 287 let the ministers of superstition tremble at finding their conspiracies discovered; let them dread the arrival of the day, when mortals, cured of those errors with which they have abused them, will no longer be enslaved by their artifice.

288 If we cannot induce nations to lay aside their inveterate prejudices, let us, at least, endeavour to prevent them from relapsing into those excesses, to the commission of which superstition has so frequently hurried them; 289 let humankind form to the self chimeras, if you

cannot do without them; let you think as you may feel inclined, provided your reveries do not make you forget that you are a human; 290 that you does not cease to remember that a sociable being is not formed to resemble the most ferocious animals. 291 Let us try to balance the fictitious interests of superstition, by the more immediate advantages of the earth. 292 Let sovereigns, as well as their subjects, at length acknowledge that the benefits resulting from truth, the happiness arising from justice, the tranquillity springing out of wholesome laws, 293 the blessings to be derived from a rational education, the superiority to be obtained from a physical, peaceable morality, are much more substantive than those they vainly expect from their respective superstitious systems. 294 Let them feel, that advantages so tangible, benefits so precious, ought not to be sacrificed to uncertain hopes, so frequently contradicted by experience.

295 In order to convince themselves of these truths, let every rational person consider the numberless crimes which superstition has caused upon our globe; 296 let them study the frightful history of theology: let them read over the biography of its more odious ministers, who have too often fanned the spirit of discord--kindled the flame of fury-- stirred up the raging fire of madness: 297 let the prince and the people, at least, sometimes learn to resist the demoniacal passions of these interpreters of unintelligible systems, which they acknowledge they do not themselves at all understand, 298 especially when they shall invoke them to be inhuman; when they shall preach up intolerance; when they invite them to barbarity; 299 above all, when they shall command them, in the name of their gods, to stifle the cries of Nature; to put down the voice of equity; to be deaf to the remonstrances of reason; to be blind to the interest of society.

NATURE

300 Feeble mortals! led astray by error, how long will ye permit your imagination, so active, so prompt to seize on the marvellous, to continue to seek out of the universe pretexts to render you baneful to yourselves, injurious to the beings with whom ye live in society? 301 Wherefore do ye not follow in peace, the simple, easy route marked out for ye by Nature? 302 To what purpose do ye scatter thorns on the road of life? What avails it, that ye multiply those sorrows to which your destiny exposes ye? 303 What advantages can ye derive from systems with which the united efforts of the whole human species have not been competent to bring ye acquainted? 304 Be content, then, to remain ignorant of that, which the human mind is not formed to comprehend; which human intellect is not adequate to embrace: 305 occupy yourselves with truth; learn the invaluable art of living happy; perfection your morals; give rationality to your governments; simplify your laws, and rest them on the pillars of justice; 306 watch over education, and see that it is of an invigorating quality; give attention to agriculture, and encourage beneficial improvements; foster those sciences which are actually useful, and place their professors in the most honourable stations; 307 labour with ardour, and munificently reward those whose assiduity promotes the general welfare; 308 oblige Nature by your industry to open Her immense stores, to become propitious to your exertions; do these things, and the gods will oppose nothing to your felicity.

309 Leave to idle thinkers, to soporific dreamers, to waking visionaries, to useless enthusiasts, the unproductive task, the unfruitful occupation, of fathoming depths, from which ye ought sedulously to divert your attention; 310 enjoy with moderation, the benefits attached to your present existence; augment their number when reason sanctions the multiplication; but never attempt to spring yourselves forward, beyond the sphere destined for your action. 311 If you must have chimeras, permit your fellow creatures to have

theirs also; but never cut the throats of your brethren, when, they cannot rave in your own manner. 312 If ye will have unintelligible systems, if ye cannot be contented without marvellous doctrines, if the infirmities of your nature require an invisible crutch, adopt such as may best suit with your humour; 313 select those which you may think most calculated to support your tottering frame; if ye can, let your own imagination give birth to them; but do not insist on your neighbours making the same choice with yourself: 314 do not suffer these imaginary theories to infuriate your mind: let them not so far intoxicate your understandings, as to make ye mistake the duties ye owe to the real beings with whom ye are associated. 315 Always remember, that amongst these duties, the foremost, the most consequential, the most immediate in its bearing upon the felicity of the human race, stands, a reasonable indulgence for the foibles of others.

DO ATHEISTS EXIST?
Paul Henri Thiery (Baron D'Holbach)

54 What has been said in the course of this work, ought sufficiently to undeceive those who are capable of reasoning on the prejudices to which they attached so much importance. 2 But the most evident truths frequently crouch under fear; are kept at bay by habit; prove abortive against the force of enthusiasm. 3 Nothing is more difficult to remove from its resting place than error, especially when long prescription has given it full possession of the human mind. 4 It is almost unassailable when supported by general consent; when it is propagated by education; when it has acquired inveteracy by custom: 5 it commonly resists every effort to disturb it, when it is either fortified by example, maintained by authority, nourished by the hopes, 6 or cherished by the fears of a people, who have learned to look upon these delusions as the most potent remedies for their sorrows. 7 Such are the united forces which sustain

the empire of unintelligible systems over the inhabitants of this world; 8 they appear to give stability to their throne; to render their power immoveable; to make their reign as lasting as the human race.

9 We need not, then, be surprised at seeing the multitude cherish their own blindness; encourage their superstitious notions; exhibit the most sensitive fear of truth. 10 Everywhere we behold mortals obstinately attached to phantoms from which they expect their happiness; notwithstanding these fallacies are evidently the source of all their sorrows. 11 Deeply smitten with the marvellous, disdaining the simple, despising that which is easy of comprehension, but little instructed in the ways of Nature, accustomed to neglect the use of their reason, 12 the uninformed, from age to age, prostrate themselves before those invisible powers which they have been taught to adore. 13 To these they address their most fervent prayers; implore them in their misfortunes, offer them the fruits of their labour; 14 they are unceasingly occupied either with thanking their vain idols for benefits they have not received at their bands, or else in requesting from them favours which they can never obtain. 15 Neither experience nor reflection can undeceive them; they do not perceive these idols, the work of their own hands, have always been deaf to their intreaties; 16 they ascribe it to their own conduct; believe them to be violently irritated: they tremble, groan out the most dismal lamentations; 17 sigh bitterly in their temples; strew their altars with presents; load their priests with their largesses; 18 it never strikes their attention that these beings, whom they imagine so powerful, are themselves submitted to Nature; are never propitious to their wishes, but when Nature Herself is favourable. 19 It is thus that nations are the accomplices of those who deceive them; are

themselves as much opposed to truth as those who lead them astray.

20 In matters of superstition, there are very few people who do not partake, more or less, of the opinions of the illiterate. 21 Every person who throws aside the received ideas, is generally considered a mad-person; is looked upon as a presumptuous being, who insolently believes the self much wiser than own associates. 22 At the magical sound of superstition, a sudden panic, a tremulous terror takes possession of the human species: 23 whenever it is attacked, society is alarmed; each individual imagines they already sees the celestial monarch lift His avenging arm against the country in which rebellious nature has produced a monster with sufficient temerity to brave these sacred opinions. 24 Even the most moderate people tax with folly, brand with sedition, whoever dares combat with these imaginary systems, the rights of which good sense has never yet examined. 25 In consequence, the person who undertakes to tear the bandeau of prejudice, appears an irrational being-- a dangerous citizen; 26 His sentence is pronounced with a voice almost unanimous; the public indignation, roused by fanaticism, stirred up by imposture, renders it impossible for Him to be heard in His defence; 27 everyone believes the self culpable, if He does not exhibit His fury against you; if He does not display His zeal in hunting you down; it is by such means human seeks to gain the favour of the angry gods, whose wrath is supposed to be provoked.

28 Thus the individual who consults own reason, the disciple of Nature, is looked upon as a public pest; the enemy to superstition is regarded as the enemy to the human race; 29 you who would establish a lasting peace amongst people, is treated as the disturber of society; 30 the person who would be disposed to cheer affrighted mortals by breaking those idols, before whom prejudice has obliged them to tremble, is unanimously proscribed as an atheist. 31 At the bare name of atheist the superstitious person quakes; the deist

is alarmed; the priest enters the judgement chair with fury glaring in own eyes; 32 tyranny prepares own funeral pile, the vulgar applaud the punishments which irrational, partial laws, decree against the true friend of the human species. 33 Such are the sentiments which every human must expect to excite, 34 who shall dare to present own fellow creatures with that truth which all appear to be in search of, but which all either fear to find, or else mistake what we are disposed to show it to them. 35 But what is this person, who is so foully calumniated as an atheist? 36 You are one who destroyeth chimeras prejudicial to the human race; who endeavours to re-conduct wandering mortals back to Nature; who is desirous to place them upon the road of experience; who is anxious that they should actively employ their reason. 37 You are a thinker, who, having meditated upon matter, its energies, its properties, its modes of acting, 38 hath no occasion to invent ideal powers, to recur to imaginary systems, in order to explain the phenomena of the universe-- to develop the operations of Nature; 39 who needs not creatures of the imagination, which far from making you better understand Nature, do no more than render it wholly inexplicable, an unintelligible mass, useless to the happiness of humankind.

40 Thus, the only people who can have pure, simple, actual ideas of Nature, are considered either as absurd or knavish speculators. 41 Those who form to themselves distinct, intelligible notions of the powers of the universe, are accused of denying the existence of this power: 42 those who found everything that is operated in this world, upon determinate, immutable laws, are accused with attributing everything to chance; 43 are taxed with blindness, branded with delirium, by those very enthusiasts themselves, whose imagination, always wandering in a vacuum, regularly attribute the effects of Nature to fictitious causes, 44 which have no existence but in their own heated brain; to

fanciful beings of their own creation; to chimerical powers, which they obstinately persist in preferring to actual, demonstrable causes. 45 No person in own proper senses can deny the energy of Nature, or the existence of a power by virtue of which matter acts; by which it puts itself in motion; 46 but no person can, without renouncing own reason, attribute this power to an immaterial substance; to a power placed out of Nature; distinguished from matter; having nothing in common with it. 47 Is it not saying, this power does not exist, to pretend that it resides in an unknown being, formed by an heap of unintelligible qualities, of incompatible attributes, from whence necessarily results a whole, impossible to have existence?

48 Indestructible elements, the atoms of Epicurus, of which it is said the motion, the collision, the combination, have produced all beings, 49 are, unquestionably, much more tangible than the numerous theological systems, broached in various parts of the earth. 50 Thus, to speak precisely, they are the partisans of imaginary theories, the advocates of contradictory beings, the defenders of creeds, impossible to be conceived, 51 the contrivers of substances which the human mind cannot embrace on any side, who are either absurd or knavish; 52 those enthusiasts, who offer us nothing but vague names, of which everything is denied, of which nothing is affirmed, are the real Atheists; 53 those, I say, who make such beings the authors of motion, the preservers of the universe, are either blind or irrational.

54 Are not those dreamers, who are incapable of attaching any one positive idea to the causes of which they unceasingly speak, true deniers? 55 Are not those visionaries, who make a pure nothing the source of all beings, people really groping in the dark? 56 Is it not the height of

folly to personify abstractions, to organise negative ideas, and then to prostrate ourselves before the figments of our own brain? 57 Nevertheless, they are people of this temper who regulate the opinions of the world; who hold up to public scorn, those who are consistent to principle; who expose to the most infuriate vengeance, those who are more rational than themselves. 58 If you will but accredit those profound dreamers, there is nothing short of madness, nothing on this side the most complete derangement of intellect, that can reject a totally incomprehensible motive-power in Nature. 59 Is it, then, delirium to prefer the known to the unknown? 60 Is it a crime to consult experience, to call in the evidence of our senses, in the examination of that which we are informed is the most important to be understood? 61 Is it a horrid outrage to address ourselves to reason; to prefer its oracles to the sublime decisions of some sophists, who themselves acknowledge they do not comprehend anything of the systems they announce?

62 Nevertheless, according to these people, there is no crime more worthy of punishment-- there is no enterprise more dangerous to morals-- no treason more substantive against society, 63 than to despoil these immaterial substances, which they know nothing about, of those inconceivable qualities which these learned doctors ascribe to them-- 64 of that equipage with which a fanatical imagination has furnished them-- of those miraculous properties with which ignorance, fear, and imposture have emulated each other in surrounding them: 65 there is nothing more impious than to call forth human's reason upon superstitious creeds; 66 nothing more heretical than to cheer up mortals against systems, of which the idea alone is the source of all their sorrows; 67 there is nothing more pious,

nothing more orthodox, than to exterminate those audacious beings who have had sufficient temerity to attempt to break an invisible charm that keeps the human species benumbed in error: 68 if we are to put faith in the asseverations of the hierarchy, to be disposed to break human's chains is to rend asunder your most sacred bonds.

69 In consequence of these clamours, perpetually renovated by the disciples of imposture, kept constantly afloat by the theologians, 70 reiterated by ignorance, those nations, which reason, in all ages, has sought to undeceive, have never dared to hearken to its benevolent lessons: they have stood aghast at the very name of physical truth. 71 The friends of humankind were never listened to, because they were the enemies to own superstition-- the examiners of the doctrines of own priest. 72 Thus the people continued to tremble; very few philosophers had the courage to cheer them; 73 scarcely any one dared brave public opinion; completely inoculated by superstition, they dreaded the power of imposture, the menaces of tyranny, which always sought to uphold themselves by delusion. 74 The yell of triumphant ignorance, the rant of haughty fanaticism, at all time stifled the feeble voice of the disciple of Nature; 75 your lessons were quickly forgotten; you was obliged to keep silence; when you even dared to speak, it was frequently only in an enigmatical language, perfectly unintelligible to the great mass of humankind. 76 How should the uninformed, who with difficulty compass the most evident truths, those that are the most distinctly announced, be able to comprehend the mysteries of Nature, presented under half words, couched under intricate emblems.

77 In contemplating the outrageous language which is excited among theologians, by the opinions of those whom they choose to call atheists; 78 in looking at the punishments which at their instigation were frequently decreed against them, should we not be authorised to

conclude, that these doctors either are not so certain as they say they are, of the infallibility of their respective systems; 79 or else that they do not consider the opinions of their adversaries so absurd as they pretend?

80 It is always either distrust, weakness, or fear, frequently the whole united, that render humans cruel; they have no anger against those whom they despise; they do not look upon folly as a punishable crime. 81 We should be content with laughing at an irrational mortal, who should deny the existence of the sun; 82 we should not think of punishing this person, unless we had, ourselves, taken leave of our senses.

83 Theological fury never proves more than the imbecility of its cause. Lucian describes Jupiter, who disputing with Menippus, is disposed to strike him to the earth with his thunder; 84 upon which the philosopher says to him, "Ah! thou vexest thyself, thou usest thy thunder! then thou art in the wrong." 85 The inhumanity of these human-monsters, whose profession it was to announce chimerical systems to nations, incontestably proves, that they alone have an interest in the invisible powers they describe; 86 of which they successfully avail themselves to terrify, mortals: 87 they are these tyrants of the mind, however, who, but little consequent to their own principles, undo with one hand that which they rear up with the other: 88 they are these profound logicians who, after having formed a deity filled with goodness, wisdom and equity, traduce, disgrace, and completely annihilate Him, by saving He is cruel, capricious, unjust, and despotic: 89 this granted, these people are truly impious; decidedly heretical.

90 You who knoweth not this system, cannot do it any injury, consequently cannot be called impious. 91 "To be impious," says Epicurus, "is not to take away from the illiterate the gods

which they have; it is to attribute to these gods the opinions of the vulgar." 92 To be impious is to insult systems which we believe; it is knowingly to outrage them. 93 To be impious, is to admit a benevolent, just God, at the same time we preach up persecution and carnage. 94 To be impious, is to deceive people in the name of a Deity, whom we make use of as a pretext for our own unworthy passions. 95 To be impious, is to speak falsely on the part of a God, whom we suppose to be the enemy of falsehood. 96 In fine, to be impious, is to make use of the name of the Divinity in order to disturb society-- to enslave it to tyrants-- to persuade human that the cause of imposture is the cause of God; 97 it is to impute to God those crimes which would annihilate His divine perfections. 98 To be impious, and irrational, at the same time, is to make, by the aggregation of discrepant qualities, a mere chimera of the God we adore.

99 On the other hand, to be pious, is to serve your country with fidelity; it is to be useful to your fellow creatures; to labour to the welfare of society. 100 Everyone can put in own claim to this piety, according to your faculties; you who meditates can render Him yourself useful, when you have the courage to announce truth-- to attack error-- 101 to battle those prejudices which everywhere oppose themselves to the happiness of humankind; 102 it is to be truly useful, it is even a duty, to wrest from the hands of mortals those homicidal weapons which wretched fanatics so profusely distribute among them; 103 it is highly praiseworthy to deprive imposture of its influence; 104 it is loving our neighbour as ourselves to despoil tyranny of its fatal empire over opinion, which at all times it so successfully employs to elevate knaves at the expense of public happiness; 105 to erect its power upon the ruins of liberty; to

establish unruly passions upon the wreck of public security. 106 To be truly pious, is religiously to observe the wholesome laws of Nature; to follow up faithfully those duties which She prescribes to us; 107 in short, to be pious is to be humane, equitable, benevolent: it is to respect the rights of humankind. 108 To be pious and rational at the same time, is to reject those reveries which would be competent to make us mistake the sober counsels of reason.

109 Thus, whatever fanaticism, whatever imposture may say, you who denieth the solidity of systems which have no other foundation than an alarmed imagination; 110 you who rejecteth creeds continually in contradiction with themselves; 111 you who banisheth from your heart, doctrines perpetually wrestling with Nature, always in hostility with reason, ever at war with the happiness of human; 112 you, I repeat, who undeceiveth yourself on such dangerous chimeras, when your conduct shall not deviate from those invariable rules which sound morality dictates, which Nature approves, which reason prescribes, may be fairly reputed pious, honest, and virtuous. 113 Because a person refuseth to admit contradictory systems, as well as the obscure oracles, which are issued in the name of the gods, does it then follow, that such a person refuses to acknowledge the evident, the demonstrable laws of Nature, 114 upon which you depends, of which you are obliged to fulfill the necessary duties, under pain of being punished in this world; whatever you may be in the in the next? 115 It is true, that if virtue could by any chance consist in an ignominious renunciation of reason, in a destructive fanaticism, in useless customs, the atheist, as you are called, could not pass for a virtuous being: 116 but if virtue actually consists in doing to society all the good of which we

are capable, this miscalled atheist may fairly lay claim to its practice: 117 your courageous, tender soul, will not be found guilty, for hurling your legitimate indignation against prejudices, fatal to the happiness of the human species.

118 Let us listen, however, to the imputations which the theologians lay upon those people they falsely denominate atheists; 119 let us coolly, without any peevish humour, examine the calumnies which they vomit forth against them: 120 it appears to them that atheism,-- as they call differing in opinion from themselves,-- is the highest degree of delirium that can assail the human mind; the greatest stretch of perversity that can infect the human heart; 121 interested in blackening their adversaries, they make incredulity the undeniable offspring of folly; the absolute effect of crime. 122 "We do not," say they to us, "see those people fall into the horrors of atheism, who have reason to hope the future state will be for them a state of happiness." 123 In short, according to these metaphysical doctors, it is the interest of their passions which makes them seek to doubt systems, at whose tribunals they are accountable for the abuses of this life; 124 it is the fear of punishment which is alone known to atheists; they are unceasingly repeating the words of a Hebrew prophet, who pretends that nothing but folly makes people deny these systems; 125 perhaps, however, if you had suppressed your negation, you would have more closely approximated the truth.

126 Doctor Bentley, in his Folly of Atheism, has let loose the whole Billingsgate of theological spleen, which he has scattered about with all the venom of the most filthy reptiles: 127 if he and other expounders are to be believed, "nothing is blacker than the heart of an atheist; nothing is more false than their mind. 128 Atheism," according to them, "can only be the offspring of a tortured conscience, that seeks to disengage itself from the cause of its trouble. 129 We have a right", says Derham, "to look upon an atheist as a monster

among rational beings; as one of those extraordinary productions which we hardly ever meet with in the whole human species; 130 and who, opposing themselves to all other people, revolts not only against reason and human nature, but against the Divinity Himself." 131 We shall simply reply to all these calumnies by saying, it is for the reader to judge if the system which these people call atheism, be as absurd as these profound speculators-- 132 who are perpetually in dispute on the uninformed, ill organised, contradictory, whimsical productions of their own brain-- would have it believed to be!

133 It is true, perhaps, that the system of naturalism hitherto has not been developed in all its extent: 134 unprejudiced people however, will, at least, be enabled to know whether the author has reasoned well or ill; 135 whether or not you have attempted to disguise the most important difficulties; distinctly to see if you have been disingenuous; they will be competent to observe if, like unto the enemies of human reason, you have recourse to subterfuges, to sophisms, to subtle discriminations, 136 which ought always to make it suspected of those who use them, either that they do not understand or else that they fear the truth. 137 It belongs then to candour, it is the province of disinterestedness, it is the duty of reason to judge, if the natural principles which have been here ushered to the world be destitute of foundation; 138 it is to these upright jurisconsults that a disciple of Nature submits own opinions: 139 you have a right to except against the judgment of enthusiasm; you have the prescription to enter your caveat against the decision of presumptuous ignorance; above all, you are entitled to challenge the verdict of interested knavery.

140 Those people who are accustomed to think, will, at least find reasons to doubt many of those marvellous notions, which appear as incontestable truths only to those, who have never assayed them by the standard of good sense. 141 We agree with Derham, that atheists are rare;

but then we also say, that superstition has so disfigured Nature, so entangled Her rights-- 142 enthusiasm has so dazzled the human mind-- terror has so disturbed the heart of human--imposture has so bewildered your imagination-- tyranny has so enslaved your thoughts: 143 in fine, error, ignorance, and delirium have so perplexed and confused the clearest ideas, that nothing is more uncommon than to find people who have sufficient courage to undeceive themselves on notions which everything conspires to identify with their very existence.

144 Indeed, many theologians in despite of those bitter invectives with which they attempt to overwhelm the people they choose to call atheists, appear frequently to have doubted whether any ever existed in the world. 145 Tertullian, who, according to modern systems, would be ranked as an atheist, because he admitted a corporeal God, says, "Christianity has dissipated the ignorance in which the Pagans were immersed respecting the divine essence, 146 and there is not an artisan among the Christians who does not see God, and who does not know Him." 147 This uncertainty of the theologic professors was, unquestionably, founded upon those absurd ideas, which they ascribe to their adversaries, 148 whom they have unceasingly accused with attributing everything to chance-- to blind causes-- to dead, inert matter, incapable of self-action.

149 We have, I think, sufficiently justified the partisans of Nature against these ridiculous accusations; 150 we have throughout the whole proved, and we repeat it, that chance is a word devoid of sense, which as well as all other unintelligible words, announces nothing but ignorance of actual causes. 151 We have demonstrated that matter is not dead; that Nature, essentially active and self-existent, has sufficient energy to produce all the beings which She contains-- all the phenomena we behold. 152 We have, throughout, made it evident that this cause is much more tangible, more easy of comprehension, than the

inconceivable theory to which theology assigns these stupendous effects. 153 We have represented, that the incomprehensibility of natural effects was not a sufficient reason for assigning to them a system still more incomprehensible than any of those of which, at least, we have a slight knowledge. 154 In fine, if the incomprehensibility of a system does not authourise the denial of its existence, it is at least certain that the incompatibility of the attributes with which it is clothed, authourises the assertion, 155 that those which unite them cannot be anything more than chimeras, of which the existence is impossible.

156 This granted, we shall be competent to fix the sense that ought to be attached to the name of atheist; which, notwithstanding, the theologians lavish on all those who deviate in anything from their opinions. 157 If, by atheist, be designated a person who denieth the existence of a power inherent in matter, without which we cannot conceive Nature, 158 and if it be to this power that the name of God is given, then there do not exist any atheists, and the word under which they are denominated would only announce fools. 159 But if by atheists be understood people without enthusiasm; who are guided by experience; who follow the evidence of their senses; 160 who see nothing in Nature but what they actually find to have existence, or that which they are capacitated to know; 161 who neither do, nor can perceive anything but matter essentially active, moveable, diversely combined, in the full enjoyment of various properties, capable of producing all the beings who display themselves to our visual faculties, 162 if by atheists be understood natural philosophers, who are convinced that without recurring to chimerical causes, they can explain everything, simply by the laws of motion; 163 by the relation subsisting between beings; by their affinities; by their analogies; by their aptitude to attraction; by their repulsive powers; by their proportions; by their combinations; by their decomposition: 164 if by atheists be meant these people who

do not understand what Pneumatology is, who do not perceive the necessity of spiritualising, or of rendering incomprehensible, those corporeal, sensible, natural causes, which they see act uniformly; 165 who do not find it requisite to separate the motive-power from the universe; 166 who do not see, that to ascribe this power to an immaterial substance, to that whose essence is from thenceforth totally inconceivable, is a means of becoming more familiar with it: 167 if by atheists are to be portrayed those people who ingenuously admit that their mind can neither receive nor reconcile the union of the negative attributes and the theological abstractions, with the human and moral qualities which are given to the Divinity; 168 or those people who pretend that from such an incompatible alliance, there could only result an imaginary being; 169 seeing that a pure spirit is destitute of the organs necessary to exercise the qualities, to give play to the faculties of human nature: 170 if by atheists are described those people who reject systems, whose odious and discrepant qualities are solely calculated to disturb the human species-- to plunge it into very prejudicial follies: 171 if, I repeat it, thinkers of this description are those who are called atheists, it is not possible to doubt their existence; 172 and their number would be considerable, if the light of sound natural philosophy was more generally diffused; 173 if the torch of reason burnt more distinctly; or if it was not obscured by the theological bushel: from thence, however, they would be considered neither as irrational; nor as furious beings, 174 but as people devoid of prejudice, of whose opinions, or if they prefer it, whose ignorance, would be much more useful to the human race, 175 than those ideal sciences, those vain hypotheses, which for so many ages have been the actual causes of all human's tribulation.

176 Doctor Cudworth, in his Intellectual System, reckons four species of atheists among the ancients.

NATURE

177 First.-- The disciples of Anaximander, called Hylopathians, who attributed everything to matter destitute of feeling. 178 His doctrine was, that humans were born of earth united with water, and vivified by the beams of the sun; 179 his crime seems to have been, that he made the first geographical maps and sun-dials; declared the earth moveable and of a cylindrical form.

180 Secondly.-- The Atomists, or the disciples of Democritus, who attribute everything, to the concurrence of atoms. 181 His crime was, having first taught that the milky way was occasioned by the confused light from a multitude of stars.

182 Thirdly.--The Stoics, or the disciples of Zeno, who admitted a blind Nature acting after certain laws. 183 His crime appears to be, that he practised virtue with unwearied perseverance, and taught that this quality alone would render humankind happy.

184 Fourthly. -- The Hylozoists, or the disciples of Strato, who attributed life to matter. 185 His crime consisted in being one of the most acute natural philosophers of his day, enjoying high favour with Ptolemy Philadelphus, an intelligent prince, whose preceptor he was.

186 If, however, by atheists, are meant those people, who are obliged to avow, that they have not one idea of the system they adore, or which they announce to others; 187 who cannot give any satisfactory account, either of the nature or of the essence of their immaterial substances; 188 who can never agree amongst themselves on the proofs which they adduce in support of their System; on the qualities or on the modes of action of their incorporeities, which by dint of negations they render a mere nothing; 189 who either prostrate themselves, or cause others to bow down, before the absurd fictions of their own delirium: 190 if, I say, by atheists, be

denominated people of this stamp, we shall be under the necessity of allowing, that the world is filled with them: 191 we shall even be obliged to place in this number some of the most active theologians, who are unceasingly reasoning upon that Which they do not understand; 192 who are eternally disputing upon points which they cannot demonstrate; 193 who by their contradictions very efficaciously undermine their own systems; 194 who annihilate all their own assertions of perfection, by the numberless imperfections with which they clothe them; 195 who rebel against their gods by the atrocious character under which they depict them. 196 In short, we shall be able to consider as true atheists, those credulous, weak people, who upon hearsay and from tradition, bend the knee before idols, 197 of whom they have no other ideas, than those which are furnished them by their spiritual guides, who themselves acknowledge that they comprehend nothing about the matter.

198 What has been said amply proves that the theologians themselves have not always known the sense they could affix to the word atheist; 199 they have vaguely attacked, in an indistinct manner, calumniated with it, those people whose sentiments and principles were opposed to their own. 200 Indeed, we find that these sublime professors, always infatuated with their own particular opinions, have frequently been extremely lavish in their accusations of atheism, against all those whom they felt a desire to injure; 201 whose characters it was their pleasure to paint in unfavourable colours; whose doctrines they wished to blacken; whose systems they sought to render odious: 202 they were certain of alarming the illiterate, of rousing the antipathies of the silly, by a loose imputation, or by a word, to which ignorance attaches the idea of horror, merely because it is

unacquainted with its true sense. 203 In consequence of this policy, it has been no uncommon spectacle to see the partisans of the same sect, the adorers of the same gods, reciprocally treat each other as atheists, in the fervour of their theological quarrels; 203 to be an atheist, in this sense, is not to have, in every point, exactly the same opinions as those with whom we dispute, either on superstitious or religious subjects. 204 In all times the uninformed have considered those as atheists, who did not think upon the Divinity precisely in the same manner as the guides whom they were accustomed to follow.

205 Socrates, the adorer of a unique God, was no more than an atheist in the eyes of the Athenian people. 206 Still more, as we have already observed, those people have frequently been accused of atheism, who have taken the greatest pains to establish the existence of the gods, but who have not produced satisfactory proofs: 207 when their enemies wished to take advantage of them, it was easy to make them pass for atheists, who had wickedly betrayed their cause, by defending it too feebly. 208 The theologians have frequently been very highly incensed against those who believed they had discovered the most forcible proof of the existence of their gods, 209 because they were obliged to discover that their adversaries could make very contrary inductions from their propositions; 210 they did not perceive that it was next to impossible not to lay themselves open to attack, in establishing principles visibly founded upon that which each human sees variously.

211 Thus Paschal says, "I have examined if this God, of whom all the world speaks, might not have left some marks of Himself. I look everywhere, and everywhere I see nothing but obscurity. 212 Nature offers one

nothing, that may not be a matter of doubt and in quietude. If I saw nothing in Nature which indicated a Divinity, I should determine with myself, to believe nothing about it. 213 If every where I saw the sign of a creator, I should repose myself in peace, in the belief of one. 214 But seeing too much to deny, and too little to assure me of His existence, I am in a situation that I lament, and in which I have an hundred times wished, that if a God doth sustain Nature, He would give unequivocal marks of it, 215 and that if the signs which He hath given be deceitful, that He would suppress them entirely; that He said all or nothing, to the end that I might see which side I ought to follow."

216 In a word, those who have most vigourously taken up the cause of the theological systems, have been taxed with atheism and irreligion; 217 the most zealous partisans have been looked upon as deserters, have been contemplated as traitors; 218 the most orthodox theologians have not been able to guarantee themselves from this reproach; they have mutually bespattered each other; prodigally lavished, with malignant reciprocity, the most abusive terms: 219 nearly all have, without doubt, merited these invectives, if in the term atheist be included those people who have not any idea of their various systems, that does not destroy itself, whenever they are willing to submit it to the touchstone of reason. 220 From whence we may conclude, without subjecting ourselves to the reproach of being hasty, that error will not stand the test of investigation; 221 that it will not pass the ordeal of comparison; that it is in its hues a perfect chameleon; that consequently it can never do more than lead to the most absurd deductions: 222 that the most ingenious systems, when they have their foundations in hallucination, crumble like dust under the rude band of the assayer; 223 that the most

sublimated doctrines, when they lack the substantive quality of rectitude, evaporate under the scrutiny of the sturdy examiner, who tries them in the crucible; 224 that it is not by levelling abusive language against those who investigate sophisticated theories, they will either be purged of their absurdities, acquire solidity, or find an establishment to give them perpetuity; 225 that moral obliquities, can never be made rectilinear by the mere application of unintelligible terms, or by the inconsiderate jumble of discrepant properties, however gaudy the assemblage: 226 in short, that the only criterion of truth is, that it is ever consistent with itself.

IS WHAT IS TERMED ATHEISM COMPATIBLE WITH MORALITY?

Paul Henri Thiery (Baron D'Holbach)

55 After having proved the existence of those whom the superstitious bigot, the heated theologian, the inconsequent theist, calls atheists, let us return to the calumnies which are so profusely showered upon them by the deicolists. 2 According to Abady, in his '*Treatise on the Truth of the Christian Religion'*, "an atheist cannot be virtuous: to him virtue is only a chimera; probity no more than a vain scruple; honesty nothing but foolishness;-- 3 he knoweth no other law than his interest: where this sentiment prevails, conscience is only a prejudice; 4 the law of Nature only an illusion; right no more than an error; benevolence hath no longer any foundation; 5 the bonds of society are loosened; the ties of fidelity are removed; friend is ready to betray friend; the citizen to deliver up his country; the son to assassinate his father, in order to enjoy his inheritance, 6 whenever they shall find occasion, and that authority or silence shall shield them from the arm of the secular power, which alone is to be feared. 7 The most inviolable rights, and most sacred

laws, must no longer be considered, except as dreams and visions."

8 Such, perhaps, would be the conduct, not of a feeling, thinking, reflecting being, susceptible of reason; 9 but of a ferocious brute, of an irrational wretch, who should not have any idea of the natural relations which subsist between beings, reciprocally necessary to each other's happiness. 10 Can it actually be supposed, that a person capable of experience, furnished with the faintest glimmerings of sound sense, would lend the self to the conduct which is here ascribed to the atheist; 11 that is to say, to a person who is conversant with the evidence of facts; who ardently seeks after truth; 12 who is sufficiently susceptible of reflection, to undeceive the self by reasoning upon those prejudices which every one strives to show you as important; which all voices endeavour to announce to you as sacred? 13 Can it, I repeat, be supposed, that any enlightened, any polished society, contains a citizen so completely blind, not to acknowledge own most natural duties; 14 so very absurd, not to admit own dearest interests; so completely besotted not to perceive the danger you incurs in incessantly disturbing your fellow creatures; or in following no other rule, than your momentary appetites?

15 Is not every human being who reasons in the least possible manner, obliged to feel that society is advantageous to the self; 16 that you hath need of assistance; that the esteem of your fellows is necessary to your own individual happiness; 17 provoked, that you have everything to fear from the wrath of your associates; that the laws menace whoever shall dare to infringe them? 18 Every person who has received a virtuous education, who has in own infancy experienced the tender cares of a parent; who has in consequence tasted the sweets of friendship; 19 who has received kindness; who knows the worth of benevolence; who sets a just value upon equity; 20 who feels the pleasure which the affection

of our fellow creatures procures for us; who endures the inconveniences which result from their aversion, who smarts under the sting which is inflicted by their scorn, 21 is obliged to tremble at losing, by own measures, such manifest advantages-- at incurring such, imminent danger. 22 Will not the hatred of others, the fear of punishment, your own contempt of yourself, disturb your repose every time that, turning, inwardly upon your own conduct, you shall contemplate it under the same perspective as does your neighbour? 23 Is there then no remorse but for those who believe in incomprehensible systems? 24 Is the idea that we are tinder the eye of beings of whom we have but vague notions, more forcible than the thought that we are viewed by our fellow humans; 25 than the fear of being detected by ourselves; than the dread of exposure; than the cruel necessity of becoming despicable in our own eyes; 26 than the wretched alternative, to be constrained to blush guiltily, when we reflect on our wild career, and the sentiments which it must infallibly inspire?

27 This granted, we shall reply deliberately to this Abady, that an atheist is a person who understands Nature, who studies Her laws; who knows their own nature; who feels what it imposes upon the self. 28 An atheist hath experience; this experience proves to you every moment that vice can injure you; that your most concealed faults, your most secret dispositions, may be detected--may display your character in open day; 29 this experience proves to you that society is useful to your happiness; 30 that your interest authoritatively demands you should attach yourself to the country that protects you, which enables you to enjoy in security the benefits of Nature; 31 everything shows you that in order to be happy you must make yourself beloved; that your parent is for you the most certain of friends; that ingratitude would remove you

from your benefactor; 32 that justice is necessary to the maintenance of every association; 33 that no person, whatever may be your power, can be content with yourself, when you knows you are an object of public hatred. 34 You who has maturely reflected upon yourself, upon your own nature, upon that of your associates, upon your own wants, upon the means of procuring them, cannot prevent yourself from becoming acquainted with your duties-- 35 from discovering the obligations you owes to yourself, as well as those which you owes to others; 36 from thence you have morality, you have actual motives to confirm yourself to its dictates; you are obliged to feel, that these duties are imperious: 37 if your reason be not disturbed by blind passions, if your mind be not contaminated by vicious habits, you will find that virtue is the surest road to felicity.

38 The atheists, as they are styled, or the fatalists, build their system upon necessity: 39 thus, their moral speculations, founded upon the nature of things, are at least much more permanent, much more invariable, 40 than those which only rest upon systems that alter their aspect according to the various dispositions of their adherents-- in conformity with the wayward passions of those who contemplate, them. 41 The essence of things, and the immutable laws of Nature, are not subject to fluctuate; 42 it is imperative with the atheist, as you are facetiously called by the theologian, to call whatever injures yourself either vice or folly; 43 to designate that which injures others, crime; to describe all that is advantageous to society, everything which contributes to its permanent happiness, virtue. 44 It will be obvious, then, that the principles of the miscalled atheist are much less liable to be shaken, than those of the enthusiast, who shall have studied a baby from own earliest Infancy; 45 who should have devoted not only your days, but your nights, to gleaning the

scanty portion of actual information that you scatters through your volumes; 46 they will have a much more substantive foundation than those of the theologian, who shall construct your morality upon the harlequin scenery of systems that so frequently change, even in your own distempered brain.

47 If the atheist, as they please to call those who differ in opinion with themselves, objects to the correctness of their systems, you cannot deny your own existence, nor that of beings similar to yourself, by whom you are surrounded; 48 you cannot doubt the reciprocity of the relations that subsist between them; you cannot question the duties which spring out of these relations; 49 Pyrrhonism, then, cannot enter your mind upon the actual principles of morality; which is nothing more than the science of the relations of beings living together in society.

50 If, however, satisfied with a barren, speculative knowledge of your duties, the atheist of the theologian should not apply them in your conduct-- 51 if, hurried along by the current of your ungovernable passions-- if, borne forward by criminal habits-- if, abandoned to shameful vices-- if, possessing a vicious temperament, which you have not been sedulous to correct-- 52 if, lending yourself to the stream of outrageous desires, you appears to forget your moral obligations, it by no means follows, either that you hath no principles, or that your principles are false: 53 it can only be concluded from such conduct, that in the intoxication of your passions, in the delirium of your habits, in the confusion of your reason, you does not give activity to doctrines grounded upon truth; 54 that you forgets to give currency to ascertained principles; that you may follow those propensities which lead you astray. 55 In this, indeed, you will have dreadfully descended to the miserable level of the

theologian, but you will nevertheless find them the partner of their folly-- the partaker of their insanity-- the companion of their crime.

56 Nothing is, perhaps, more common among people, than a very marked discrepancy between the mind and the heart; 57 that is to say, between the temperament, the passions, the habits the caprices, the imagination, and the judgment, assisted by reflection. 58 Nothing is, in fact, more rare, than to find these harmoniously running upon all fours with each other; it is, however, only when they do, that we see speculation influence practice. 59 The most certain virtues are those which are founded upon the temperament of human. 60 Indeed, do we not every day behold mortals in contradiction with themselves? 61 Does not their more sober judgment unceasingly condemn the extravagances to which their undisciplined passions deliver them up? 62 In short, doth not everything prove to us hourly, that people, with the very best theory, have sometimes the very worst practice; that others with the most vicious theory, frequently adopt the most amiable line of conduct? 63 In the blindest systems, in the most atrocious superstitions, in those which are most contrary to reason, we meet with virtuous people, 64 the mildness of whose character, the sensibility of whose hearts, the excellence of whose temperament, re-conducts them to humanity, makes them fall back upon the laws of Nature, in despite of their furious theories.

65 Among the adorers of the most cruel, vindictive, jealous gods, are found peaceable, souls, who are enemies to persecution; 66 who set their faces against violence; who are decidedly opposed to cruelty: among the disciples of a God filled with mercy, abounding in clemency, are seen barbarous monsters; inhuman cannibals: 67 nevertheless, both the one and the other acknowledge, that their gods ought to serve them for a model. 68 Wherefore, then, do they not in all things conform themselves? 69 It is because the most wicked systems cannot always corrupt a

virtuous soul; 70 that those which are most bland, most gentle in their precepts, cannot always restrain hearts driven along by the impetuosity of vice. 71 The organisation will, perhaps, be always more potential than either superstition or religion. 72 Present objects, momentary interests, rooted habits, public opinion, have much more efficacy than unintelligible theories, than imaginary systems, which themselves depend upon the organic structure of the human frame.

73 The point in question then is, to examine if the principles of the atheist, as you are erroneously called, be true, and not whether your conduct be commendable? 74 An atheist, having an excellent theory, founded upon Nature, grafted upon experience, constructed upon reason, who delivers the self up to excesses, dangerous to the self, injurious to society, is, without doubt, an inconsistent person. 75 But you are not more to be feared than a superstitious bigot; than a zealous enthusiast; 76 or than even a religious person who, believing in a good, confiding in an equitable, relying on a perfect God, does not scruple to commit the most frightful devastations in His name. 77 An atheistical tyrant would assuredly not be more to be dreaded than a fanatical despot. 78 An incredulous philosopher, however, is not so mischievous a being as an enthusiastic priest, who either fans the flame of discord among own fellow subjects, or rises in rebellion against own legitimate monarch.

79 Would, then, an atheist clothed with power, be equally dangerous as a persecuting priest-ridden king; as a savage inquisitor; as a whimsical devotee; or, as a morose bigot? 80 These are assuredly more numerous in the world than atheists, as they are ludicrously termed, whose opinions, or whose vices are far from being in a condition to have an influence upon society; 81 which is ever

too much hoodwinked by the priest, too much blinded by prejudice, too much the slave of superstition, to be disposed to give them a patient hearing.

82 An intemperate, voluptuous atheist, is not more dangerous to society than a superstitions bigot, who knows how to connect licentiousness, punic faith, ingratitude, libertinism, corruption of morals, with own theological notions. 83 Can it, however, be ingeniously imagined, that a person, because you are falsely termed an atheist, or because you does not subscribe to the vengeance of the most contradictory systems, will therefore be a profligate debaucheé, malicious, and persecuting; 84 that you will corrupt the wife of your friend; will turn your own wife adrift; 85 will consume both your time and your money in the most frivolous gratifications; will be the slave to the most childish amusements; the companion of the most dissolute people; 86 that you will discard all your old friends; that you will select your bosom confidants from the brazen betrayers of their native land-- from among the hoary despoilers of connubial happiness--from out of the ranks of veteran gamblers; 87 that you will either break into your neighbour's dwelling, or cut their throat; 88 in short, that you will lend yourself to all those excesses, the most injurious to society, the most prejudicial to yourself, the most deserving public castigation?

89 The blemishes of an atheist, then, as the theologian styles you, have not anything more extraordinary in them than those of the superstitious person; they possess nothing with which their doctrine can be fairly reproached. 90 A tyrant, who should be incredulous, would not be a more incommodious scourge to own subjects, than a theological autocrat, who should wield own sceptre to the misery of own people. 91 Would the nation of the latter feel more happy, from the mere circumstance that the tiger who governed it believed in the most abstract systems, heaped the most sumptuous presents on the priests, and humiliated the self at

their shrine? 92 At least it must be acknowledged, according to the showing of the theologian themselves, that under the dominion of the atheist, a nation would not have to apprehend superstitious vexations; 93 to dread persecutions for opinion; to fear proscriptions for ill-digested systems; neither would it witness those strange outrages that have sometimes been Committed for the interests of heaven, even under the mildest monarchs. 94 If it was the victim to the turbulent passions of an unbelieving prince, the sacrifice to the folly of a sovereign who should be an infidel, it would not, at least, suffer from your blind infatuation, for theological systems which you does not understand; 95 nor from your fanatical zeal, which of all the passions that infest monarchs, is ever the most destructive, always the most dangerous. 96 An atheistical tyrant, who should persecute for opinions, would be a person not consistent with own principles; 97 you could not exist; you would not, indeed, according to the theologian, be an atheist at most, 98 you would only furnish one more example, that mortals much more frequently follow the blind impulse of their passions, the more immediate stimulus of their interest, the irresistible torrent of their temperament, than their speculations, however grave, however wise. 99 It is, at least, evident, that an atheist has one pretext less than a credulous prince, for exercising own natural wickedness.

100 Indeed, if people condescended to examine things coolly, they would find that on this earth the name of God is but too frequently made use of as a motive to indulge the worst of human passions. 101 Ambition, imposture, and tyranny, have often formed a league to avail themselves of its influence, to the end that they might blind the people, and bend them beneath a galling yoke: 102 the monarch sometimes employs it to give a divine lustre to own person-- the sanction of heaven to own rights-- the confidence of its votaries to own most unjust, most

extravagant whims. 103 The priest frequently uses it to give currency to own pretensions, to the end that they may with impunity gratify own avarice, minister to own pride, secure own independence. 104 The vindictive, enraged, superstitious being, introduces the cause of own gods, that they may give free scope to their fury, which they qualifies with zeal. 105 In short, superstition becomes dangerous, because it justifies those passions, lends legitimacy to those crimes, holds forth as commendable those excesses, of which it does not fail to gather the fruit: 106 according to its ministers, everything is permitted to revenge the most high: thus the name of the Divinity is made use of to authourise the most baneful actions, to palliate the most injurious transgressions. 107 The atheist, as you are called, when you commits crimes, cannot, at least, pretend that it is your gods who command them, or who clothe them with the mantle of their approval, 108 this is the excuse the superstitious being offers for own perversity; the tyrant for own persecutions; the priest for own cruelty, and for own sedition; the fanatic for the ebullition of own boiling passions; the penitent for own inutility.

109 "They are not," says Bayle, "the general opinions of the mind, but the passions, which determine us to act." 110 Atheism, as it is called, is a system which will not make a good person wicked but it may, perhaps, make a wicked person good. 111 "Those," says the same author, "who embraced the sect of Epicurus, did not become debaucheés because they had adopted the doctrine of Epicurus; they only lent themselves to the system, then badly understood, because they were debaucheés." 112 In the same manner, a perverse person may embrace atheism, because you will flatter yourself, that this system will give full scope to your passions:

you will nevertheless be deceived. 113 Atheism, as it is called, if well understood, is founded upon Nature and upon reason, which never can, like superstition, either justify or expiate the crimes of the profligate.

114 From the diffusion of doctrines which make morality depend upon unintelligible, incomprehensible systems, that are proposed to human for a model, there has unquestionably resulted very great inconvenience. 115 Corrupt souls, in discovering, how much each of these suppositions are erroneous or doubtful, give loose to the rein of their vices, and conclude there are not more substantive motives for acting well; 116 they imagine that virtue, like these fragile systems, is merely chimerical; that there is not any cogent solid reason for practising it in this world.

117 Nevertheless, it must be evident, that it is not as the disciples of any particular tenet, that we are bound to fulfill the duties of morality; 118 it is as humans, living together in society, as sensible beings seeking to secure to ourselves a happy existence, that we should feel the moral obligation. 119 Whether these systems maintain their ground, or whether they do not, our duties will remain the same; 120 our nature, if consulted, will incontestably prove, that vice is a decided evil, that virtue is an actual, a substantial good. 121 If, then, there be found atheists who have denied the distinction of good and evil, or who have dared to strike at the foundations of morality; we ought to conclude, that upon this point they have reasoned badly; 122 that they have neither been acquainted with the nature of human, nor known the true source of human duties; 123 that they have falsely imagined that ethics, as well as theology, was only an ideal science; 124 that the fleeting systems once destroyed, there no

longer remained any bonds to connect mortals.

125 Nevertheless, the slightest reflection would have incontestably proved, that morality is founded upon immutable relations subsisting between sensible, intelligent, sociable beings; 126 that without virtue, no society can maintain itself; that without putting the curb on your desires, no mortal can conserve the self: 127 human is constrained from own nature to love virtue, to dread crime, by the same necessity that obliges you to seek happiness, and fly from sorrow: 128 thus Nature compels you to place a distinction between those objects which please, and those objects Which injure you. 129 Ask a person, who is sufficiently irrational to deny the difference between virtue and vice, if it would be indifferent to you to be beaten, robbed, calumniated, treated with ingratitude, dishonoured by your spouse, insulted by your children, betrayed by your friend? 130 Your answer will prove to you, that whatever you may say, you discriminates the actions of humankind; 131 that the distinction between good and evil, does not depend either upon the conventions of humans, or upon the ideas which they may have of particular systems; upon the punishments or upon the recompences which attend mortals in a future existence.

132 On the contrary, an atheist, as you are denominated, who should reason with justness, would feel the self more interested than another in practising those virtues to which you finds your happiness attached in this world. 133 If your views do not extend themselves beyond the limits of your present existence, you must, at least, desire to see your days roll on in happiness and in peace. 134 Every person, who during the calm of own passions, falls back upon the self, will feel that own interest invites the self to own

preservation; 135 that your felicity rigorously demands you should take the necessary means to enjoy life peaceably that it becomes an imperative duty to yourself to keep your actual abode free from alarm; your mind untainted by remorse. 136 Human oweth something to human, not merely because you would offend any particular system, if you was to injure your fellow creature; 137 but because in doing you an injury you would offend a person; would violate the laws of equity; in the maintenance of which every human being finds the self interested.

138 We every day see people who are possessed of great talents, who have very extensive knowledge, who enjoy very keen penetration, join to these advantages a very corrupt heart; who lend, themselves to the most hideous vices: 139 their opinions may be true in some respects, false in a great many others; their principles may be just, but their inductions are frequently defective; very often precipitate. 140 A person may embrace sufficient knowledge to detect some of own errors, yet command too little energy to divest the self of own vicious propensities. 141 Human is a being whose character depends upon own organisation, modified by habit--upon own temperament, regulated by education-- upon own propensities, marshalled by example-- upon own passions; guided by own government; 142 in short, you are only what transitory or permanent circumstances make you: 143 your superstitious ideas are obliged to yield to this temperament; your imaginary systems feel a necessity to accommodate themselves to your propensities; your theories give way to your interests.

144 If the system which constitutes human an atheist in the eyes of this theologic friend, does not remove you from the

vices with which you was anteriorly tainted, neither does it tincture you with any new ones; 145 whereas, superstition furnishes its disciples with a thousand pretexts for committing evil without repugnance; induces them even to applaud themselves for the commission of crime. 146 Atheism, at least, leaves people such as they are; it will neither increase a person's intemperance, nor add to your debaucheries, it will not render you more cruel than your temperament before invited you to be: 147 whereas superstition either lacks the rein to the most terrible passions, gives loose to the most abominable suggestions, or else procures easy expiations for the most dishonourable vices. 148 "Atheism," says Chancellor Bacon, "leaves to human reason, philosophy, natural piety, laws, reputation, and everything that can serve to conduct you to virtue; 149 but superstition destroys all these things, and erects itself into a tyranny over the understandings of humans: 150 this is the reason why atheism never disturbs the government, but renders human more clear-sighted, as seeing nothing beyond the bounds of this life." 151 The same author adds, "that the times in which people have turned towards atheism, have been the most tranquil; 152 whereas superstition has always inflamed their minds, and carried them on to the greatest disorders; because it infatuates the people with novelties, which wrest from and carry with them all the authority of government."

153 People, habituated to meditate, accustomed to make study a pleasure, are not commonly dangerous citizens: whatever may be their speculations, they never produce sudden revolutions upon the earth. 154 The winds of the people, at all times susceptible to be inflamed by the marvellous, their dormant passions liable to be aroused by enthusiasm, obstinately resist the light of simple truths; 155 never heat themselves for systems that demand

a long train of reflection-- that require the depth of the most acute reasoning.

156 The system of atheism, as the priests choose to denominate it, can only be the result of long meditation; the fruit of connected study; the produce of an imagination cooled by experience: it is the child of reason. 157 The peaceable Epicurus never disturbed Greece; his philosophy was publicly taught in Athens during many centuries; 158 he was in incredible favour with his countrymen, who caused statues to be erected to him; he had a prodigious number of friends, and his school subsisted for a very long period. 159 Cicero, although a decided enemy to the Epicureans, gives a brilliant testimony to the probity both of Epicurus and his disciples, who were remarkable for the inviolable friendship they bore each other. 160 In the time of Marcus Aurelius, there was at Athens a public professor of the philosophy of Epicurus, paid by that emperor, who was himself a stoic. 161 Hobbes did not cause blood to flow in England, although in his time, religious fanaticism made a king perish on the scaffold. 162 The poem of Lucretius caused no civil wars in Rome; the writings of Spinoza did not excite the same troubles in Holland as the disputes of Gomar and D'Arminius.

163 In short, we can defy the enemies to human reason to cite a single example, which proves in a decisive manner that opinions purely philosophical, or directly contrary to superstition, have ever excited disturbances in the state. 164 Tumults have generally arisen from theological notions, because both princes and people have always foolishly believed they ought to take a part in them. 165 There is nothing so dangerous as that empty philosophy, which the theologians have combined with their systems. 166 It is to philosophy, corrupted by priests, that it peculiarly belongs to blow up the embers of discord; to invite the people to rebellion; to drench the earth with human blood. 167 There is, perhaps, no theological question, which has not been the source of immense mischief to

human; 168 whilst all the writings of those denominated atheists, whether ancient or modern, have never caused any evil but to their authors; whom dominant imposture has frequently immolated at their deceptive shrine.

169 The principles of atheism are not formed for the mass of the people, who are commonly under the tutelage of their priests; 170 they are not calculated for those frivolous capacities, not suited to those dissipated minds, who fill society with their vices, who hourly afford evidence of their own inutility; 171 they will not gratify the ambitious; neither are they adapted to intriguers, nor fitted for those restless beings who find their immediate interest in disturbing the harmony of the social compact: 172 much less are they made for a great number of people, who, enlightened in other respects, have not sufficient courage to divorce themselves from the received prejudices.

173 So many causes unite themselves to confirm human in those errors which you draws in with your mother's milk, that every step that removes you from these endeared fallacies, costs you uncommon pain. 174 Those people who are most enlightened, frequently cling on some side to the general prepossession. 175 By giving up these revered ideas, we feel ourselves, as it were, isolated in society: 176 whenever we stand alone in our opinions, we no longer seem to speak the language of our associates; we are apt to fancy ourselves placed on a barren, desert island, in sight of a populous, fruitful country, which we can never reach: 177 it therefore requires great courage to adopt a mode of thinking that has but few approvers. 178 In those countries where human knowledge has made some progress; where, besides, a certain freedom of thinking is enjoyed, may easily be found a great number of deicolists, theists, 179 or incredulous beings, who, contented with having trampled underfoot the grosser

prejudices of the illiterate, have not dared to go back to the source-- to cite the more subtle systems before the tribunal of reason.

180 If these thinkers did not stop on the road, reflection would quickly prove to them that those systems which they have not the fortitude to examine, are equally injurious to sound ratiocination, 181 fully as revolting to good sense, quite as repugnant to the evidence of experience, as any of those doctrines, mysteries, fables, or superstitious customs, of which they have already acknowledged the futility; 182 they would feel, as we have already proved, that all these things are nothing more than the necessary consequences of those primitive errors which human has indulged for so many ages in succession; 183 that in admitting these errors, they no longer have any rational cause to reject the deductions which the imagination has drawn from them. 184 A little attention would distinctly show them, that it is precisely these errors that are the true cause of all the evils of society; 185 that those endless disputes, those sanguinary quarrels, to which superstition and the spirit of party every instant give birth, are the inevitable effects of the importance they attach to errors which possess all the means of distraction, that scarcely ever fail to put the mind of human into a state of combustion. 186 In short, nothing is more easy than to convince ourselves that imaginary systems, not reducible to comprehension, which are always painted under terrific aspects, must act upon the imagination in a very lively manner, 187 must sooner or later produce disputes-- engender enthusiasm-- give birth to fanaticism-- end in delirium.

188 Many people acknowledge, that the extravagances to which superstition lends activity, are real evils; 189 many complain of the abuse of superstition, but there are

very few who feel that this abuse, together with the evils, are the necessary consequences of the fundamental principles of all superstition; 190 which are founded upon the most grievous notions, which rest themselves on the most tormenting opinions. 191 We daily see people undeceived upon superstitious ideas, who nevertheless pretend that this superstition "is salutary for the people;" that without its supernatural magic, they could not be kept within due bounds; 192 in other words, could not be made the voluntary slaves of the priest.

193 But, to reason thus, is it not to say, poison is beneficial to humankind, that therefore it is proper to poison them, to prevent them from making an improper use of their power? 194 Is it not in fact to pretend it is advantageous to render them absurd; that it is a profitable course to make them extravagant; wholesome to give them an irrational bias; 195 that they have need of hobgoblins to blind them; require the most incomprehensible systems to make them giddy; 196 that it is imperative to submit them either to impostors or to fanatics, who will avail themselves of their follies to disturb the repose of the world? 197 Again, is it an ascertained fact, does experience warrant the conclusion, that superstition has a useful influence over the morals of the people?

198 It appears much more evident, is much better borne out by observation, falls more in with the evidence of the senses, that it enslaves them without rendering them better; 199 that it constitutes an herd of ignorant beings, whom panic terrors keep under the yoke of their task-masters; 200 whom their useless fears render the wretched instruments of towering ambition--of rapacious tyrants; of the subtle craft of designing priests: 201 that it forms stupid slaves, who are acquainted with no other virtue, save a blind submission to the most futile customs, to which they attach a much more substantive value than to the actual virtues springing out of the duties of morality; 202 or issuing from the social compact which has

never been made known to them. 203 If by any chance, superstition does restrain some few individuals, it has no effect on the greater number, who suffer themselves to be hurried along by the epidemical vices with which they are infected: 204 they are placed by it upon the stream of corruption, and the tide either sweeps them away, or else, swelling the waters, breaks through its feeble mounds, and involves the whole in one undistinguished mass of ruin. 205 It is in those countries where superstition has the greatest power, that will always be found the least morality.

206 Virtue is incompatible with ignorance; it cannot coalesce with superstition; it cannot exist with slavery: 207 slaves can only be kept in subordination by the fear of punishment; ignorant children are for a moment intimidated by imaginary terrors. 208 But freemen, the children of truth, have no fears but of themselves; are neither to be lulled into submission by visionary duties, nor coerced by fanciful systems; 209 they yield ready obedience to the evident demonstrations of virtue; are the faithful, the invulnerable supporters of solid systems; cling with ardour to the dictates of reason; 210 form impenetrable ramparts round their legitimate sovereigns; and fix their thrones on an immoveable basis, unknown to the theologian; 211 that cannot be touched with unhallowed hands; whose duration will be commensurate with the existence of time itself.

212 To form freemen, however, to have virtuous citizens, it is necessary to enlighten them; it is incumbent to exhibit truth to them; it is imperative to reason with them; it is indispensable to make them feel their interests; it is paramount to learn them to respect themselves; 213 they must be instructed to fear shame; they must be excited to have a just idea of honour; they must be made familiar with the value of virtue, they must be shown substantive motives for following its lessons. 214 How can these happy effects ever be expected from the polluted fountains of superstition, whose waters do

nothing more than degrade humankind? 215 Or how are they to be obtained from the ponderous, bulky yoke of tyranny, which proposes nothing more to itself, than to vanquish them by dividing them; 216 to keep them in the most abject condition by means of lascivious vices, and the most detestable crimes?

217 The false idea, which so many people have of the utility of superstition, which they, at least, judge to be calculated to restrain the licentiousness of the illiterate, arise from the fatal prejudice that it is a useful error; that truth may be dangerous. 218 This principle has complete efficacy to eternise the sorrows of the earth: 219 whoever shall have the requisite courage to examine these things, will without hesitation acknowledge, that all the miseries of the human race are to be ascribed to own errors; 220 that of these, superstitious error must be the most prejudicial, from the importance which is usually attached to it; from the haughtiness with which it inspires sovereigns; from the worthless condition which it prescribes to subjects; from the phrenzy which it excites among the vulgar.

221 We shall, therefore, be obliged to conclude, that the superstitious errors of human, rendered sacred by time, are exactly those which for the permanent interest of humankind, for the well-being of society, for the security of the monarch, demand the most complete destruction; 222 that it is principally to their annihilation, the efforts of a sound philosophy ought to be directed. 223 It is not to be feared, that this attempt will produce either disorders or revolutions: the more freedom shall accompany the voice of truth, the more convincing it will appear; 224 although the more simple it shall be, the less it will influence people, who are only smitten with the marvellous; 225 even those individuals who most

sedulously seek after truth, who pursue it with the greatest ardour, have frequently an irresistible inclination, that urges them on, and incessantly disposes them to reconcile error with its antipodes. 226 That great master of the art of thinking, who holds forth to own disciples such able advice, says, with abundant reason, "that there is nothing but a good and solid philosophy, which can, like another Hercules, exterminate those monsters called popular errors: 227 it is that alone which can give freedom to the human mind."

228 Here is, unquestionably, the true reason why atheism, as it is called, of which hitherto the principles have not been sufficiently developed, appears to alarm even those people who are the most destitute of prejudice. 229 They find the interval too great between vulgar superstition and an absolute renunciation of it; they imagine they take a wise medium in compounding with error; they therefore reject the consequences, while they admit the principle; 230 they preserve the shadow and throw away the substance, without foreseeing that, sooner or later, it must, by its obstetric art, usher into the world, one after another, the same follies 231 which now fill the heads of bewildered human beings, lost in the labyrinths of incomprehensible systems. 232 The major part of the incredulous, the greater number of reformers, do no more than prune a cankered tree, to whose root they dare not apply the axe; they do not perceive that this tree will in the end produce the same fruit.

233 Theology, or superstition, will always be an heap of combustible matter: brooded in the imagination of humankind, it will always finish by causing the most terrible explosions. 234 As long as the sacerdotal order shall have the privilege of infecting youth-- of habituating their minds to tremble before unmeaning words-- of alarming

nations with the most terrific systems, so long will fanaticism be master of the human mind; 235 imposture will, at its pleasure, cast the apple of discord among the members of the state. 236 The most simple error, perpetually fed, unceasingly modified, continually exaggerated by the imagination of human, will by degrees assume a collossal figure, sufficiently powerful to upset every institution; amply competent to the overthrow of empires. 237 Theism is a system at which the human mind cannot make a long sojourn; founded upon error, it will, sooner or later, degenerate into the most absurd, the most dangerous superstition.

238 Many incredulous beings, many theists, are to be met with in those countries where freedom of opinion reigns; that is to say, where the civil power has known how to balance superstition. 239 But, above all, atheists as they are termed, will be found in those nations where, superstition, backed by the sovereign authority, most enforces the ponderousity of its yoke; most impresses the volume of its severity; imprudently abuses its unlimited power. 240 Indeed, when in these kind of countries, science, talents, the seeds of reflection, are not entirely stifled, the greater part of the people who think, revolt at the crying abuses of superstition; 241 are ashamed of its multifarious follies; are shocked at the corruption of its professors; scandalised at the tyranny of its priests: are struck with horror at those massive chains which it imposes on the credulous. 242 Believing with great reason, that they can never remove themselves too far from its savage principles, the system that serves for the basis of such a creed, becomes as odious as the superstition itself; 243 they feel that terrific systems can only be detailed by cruel ministers; these become detestable objects to every enlightened, to every honest mind, 244 in which either

the love of equity, or the sacred fire of freedom resides; to everyone who is the advocate of humanity-- the indignant spurner of tyranny. 245 Oppression gives a spring to the soul; it obliges human to examine closely into the cause of own sorrows; misfortune is a powerful incentive, that turns the mind to the side of truth. 246 How formidable a foe must not outraged reason be to falsehood? 247 It at least throws it into confusion, when it tears away its mask; when it follows it into its last entrenchment; when it proves, beyond contradiction, that nothing is so dastardly as delusion detected, or tyrannic power held at bay.

OF THE MOTIVES WHICH LEAD TO WHAT IS FALSELY CALLED ATHEISM

Paul Henri Thiery (Baron D'Holbach)

56 The reflections, as well as the facts which have preceded, will furnish a reply to those who inquire what interest human has in not admitting unintelligible systems? 2 The tyrannies, the persecutions, the numberless outrages committed under these systems; the stupidity, the slavery, into which their ministers almost everywhere plunge the people; 3 the sanguinary disputes to which they give birth; the multitude of unhappy beings with which their fatal notions fill the world; 4 are surely abundantly sufficient to create the most powerful, the most interesting motives, 5 to determine all sensible people, who possess the faculty of thought, to examine into the authenticity of doctrines, which cause so many serious evils to the inhabitants of the earth.

6 A theist, very estimable for own talents, asks, "if there can be any other cause than an evil disposition, which can make people atheists?" 7 I reply to him, yes, there are other causes. There is the desire, a very laudable one, of having a knowledge of interesting truths; 8 there is the

powerful interest of knowing what opinions we ought to hold upon the object which is announced to us as the most important; 9 there is the fear of deceiving ourselves upon systems which are occupied with the opinions of humankind, which do not permit you should deceive yourself respecting them with impunity. 10 But when these motives, these causes, should not subsist, is not indignation, 11 or if they will, an evil disposition, a legitimate cause, a good and powerful motive, for closely examining the pretensions, for searching into the rights of systems, in whose name so many crimes are perpetrated? 12 Can any person who feels, who thinks, who has any elasticity in own soul, avoid being incensed against austere theories, which are visibly the pretext, undeniably the source, of all those evils, which on every side assail the human race? 13 Are they not these fatal systems which are at once the cause and the ostensible reason of that iron yoke that oppresses humankind; 14 of that wretched slavery in which you lives; of that blindness which hides from you your happiness; of that superstition, which disgraces you; of those irrational customs which torment you; of those sanguinary quarrels which divide you; of all the outrages which you experiences? 15 Must not every breast in which humanity is not extinguished, irritate itself against that theoretical speculation, which in almost every country is made to speak the language of capricious, inhuman, irrational tyrants?

16 To motives so natural, so substantive, we shall join those which are still more urgent, more personal to every reflecting human: 17 namely, that benumbing terror, that incommodious fear, which must be unceasingly nourished by the idea of capricious theories, 18 which lay human open to the most severe penalties, even for secret thoughts, over which you yourself has not any control; 19 that dreadful anxiety

arising out of inexorable systems, against which you may sin without even your own knowledge; of morose doctrines, the measure of which you can never be certain of having fulfilled; 20 which so far from being equitable, make all the obligations lay on one side; 21 which with the most ample means of enforcing restraint, freely permit evil, although they hold out the most excruciating punishments for the delinquents? 22 Does it not then, embrace the best interests of humanity, become of the highest importance to the welfare of humankind, of the greatest consequence to the quiet of your existence, to verify the correctness of these systems? 23 Can anything be more rational than to probe to the core these astounding theories? 24 Is it possible that anything can be more just, than to inquire rigourously into the rights, sedulously to examine the foundations, to try by every known test, the stability of doctrines, that involve in their operations, consequences of such colossal magnitude; 25 that embrace, in their dictatory mandates, matters of such high behest; that implicate the eternal felicity of such countless millions in the vortex of their action?

26 Would it not be the height of folly to wear such a tremendous yoke without inquiry; to let such overwhelming notions pass current unauthenticated; 27 to permit the soi-disant ministers of these terrific systems to establish their power, without the most ample verification of their patents of mission? 28 Would it, I repeat, be at all wonderful, if the frightful qualities of some of these systems, as exhibited by their official expounders, whom the accredited functionaries of similar systems, do not scruple, in the face of day, 29 to brand as impostors, should induce rational beings to drive them entirely from their hearts; to shake off such an intolerable burden of misery; 30 to even deny the existence of such appalling doctrines, of such petrifying systems, which the superstitious themselves, whilst paying them their homage, frequently curse from the very bottom of their hearts?

31 The theist, however, will not fail to tell the atheist, as you calls them, that these systems are not such as superstition paints them; that the colours are coarse, too glaring, ill assorted, the perspective out of all keeping; 32 you will then exhibit your own picture, in which the tints are certainly blended with more mellowness, the colouring of a more pleasing hue, the whole more harmonious, but the distances equally indistinct: 33 the atheist, in reply, will say, that superstition itself, with all the absurd prejudices, all the mischievous notions to which it gives birth, are only corollaries drawn from the fallacious ideas, from those obscure principles, which the deicolist indulges. 34 That your own incomprehensible system authourise the incomprehensible absurdities, the inconceivable mysteries, with which superstition abounds; 35 that they flow consecutively from your own premises; that when once the mind of mortals is bewildered in the dark, inextricable mazes of an ill-directed imagination, it will incessantly multiply its chimeras. 36 To assure the repose of humankind, fundamental errors must be annihilated; that you may understand your true relations, be acquainted with your imperative duties, primary delusions must be rectified; 37 to procure you that serenity of soul, without which there can be no substantive happiness, original fallacies must be undermined. 38 If the systems of the superstitious be revolting, if their theories be gloomy, if their dogmas are unintelligible, those of the theist will always be contradictory; 39 will prove fatal, when you shall be disposed to meditate upon them; will become the source of illusions, with which, sooner or later, imposture will not omit to abuse your credulity. 40 Nature alone, with the truths She discovers, is capable of lending to the human mind that firmness which falsehood will never be able to shake; to the human heart that self-possession, against which imposture will in vain direct its attacks.

41 Let us again reply to those who unceasingly repeat that the

interest of the passions alone conduct human to what is termed atheism: 42 that it is the dread of future punishment that determines corrupt individuals to make the most strenuous efforts to break up a system they have reason to dread. 43 We shall, without hesitation, agree that it is the interest of human's passions which excites you to make inquiries; 44 without interest, no person is tempted to seek; without passion, no person will seek vigourously.

45 The question, then, to be examined, is, if the passions and interests, which determine some thinkers to dive into the stability or the systems held forth to their adoption, are or are not legitimate? 46 These interests have, already been exposed, from which it has been proved, that every rational person finds in own inquietudes, in own fears, reasonable motives to ascertain, whether or not it be necessary to pass own life in perpetual dread; in never ceasing agonies? 47 Will it be said, that an unhappy being, unjustly condemned to groan in chains, has not the right of being willing to render them asunder; 48 to take some means to liberate the self from own prison; to adopt some plan to escape from those punishments, which every instant threaten you? 49 Will it be pretended that your passion for liberty has no legitimate foundation, that you does an injury to the companions of your misery, in withdrawing yourself from the shafts of tyrannical infliction; or in furnishing them also with means to escape from its cruel strokes? 50 Is, then, an incredulous person, anything more than one who has taken flight from the general prison, in which despotic superstition detains nearly all humankind? 51 Is not an atheist, as you are called, who writes, one who has broken own fetters, who supplies to those of own associates who have sufficient courage to follow you, the means of setting themselves free from the terrors that menace them?

52 The priests unceasingly repeat that it is pride, vanity, the desire of

distinguishing the self from the generality of humankind, that determines human to incredulity. 53 In this they are like some of those wealthy mortals, who treat all those as insolent who refuse to cringe before them. 54 Would not every rational person have a right to ask the priest, where is thy superiority in matters of reasoning? What motives can I have to submit my reason to thy delirium? 55 On the other hand, may it not be said to the hierarchy, that it is interest which makes them priests; that it is interest which renders them theologians; 56 that it is for the interest of their passions, to inflate their pride, to gratify their avarice, to minister to their ambition, that they attach themselves to systems, of which they alone reap the benefits? 57 Whatever it may be, the priesthood, contented with exercising their power over the illiterate, ought to permit those people who do think, to be excused from bending the knee before their vain, illusive idols.

58 We also agree, that frequently the corruption of morals, a life of debauchery, a licentiousness of conduct, even levity of mind, may conduct human to incredulity; 59 but is it not possible to be a libertine, to be irreligious, to make a parade of incredulity, without being on that account an atheist? 60 There is unquestionably a difference between those who are led to renounce belief in unintelligible systems by dint of reasoning, and those who reject or despise superstition, only because they look upon it as a melancholy object, or an incommodious restraint. 61 Many people, no doubt, renounce received prejudices, through vanity or upon hearsay; 62 these pretended strong minds have not examined anything for themselves; they act upon the authority of others, whom they suppose to have weighed things more maturely. 63 This kind of incredulous beings, have not, then, any distinct ideas, any substantive opinions, and are but little capacitated to reason for themselves; they are indeed hardly in a state to follow the reasoning of others. 64 They are irreligious in the same manner as the majority of humankind

are superstitious, that is to say, by credulity like the people; or through interest like the priest. 65 A voluptuary devoted to own appetites; a debaucheé drowned in drunkenness; an ambitious mortal given up to own schemes of aggrandisement; an intriguer surrounded by own plots; 66 a frivolous, dissipated mortal, absorbed by own gewgaws, addicted to own puerile pursuits, buried in own filthy enjoyments; a loose woman abandoned to her irregular desires; 67 a choice spirit of the day: are these I say, personages, actually competent to form a sound judgment of superstition, which they have never examined? 68 Are they in a condition to maturely weigh theories that require the utmost depth of thought? 69 Have they the capabilities to feel the force of a subtle argument; to compass the whole of a system: to embrace the various ramifications of an extended doctrine?

70 If some feeble scintillations occasionally break in upon the cimmerian darkness of their minds; 71 if by any accident they discover some faint glimmerings of truth amidst the tumult of their passions; 72 if occasionally a sudden calm, suspending, for a short season, the tempest of their contending vices, permits the bandeau of their unruly desires by which they are blinded, to drop for an instant from their hoodwinked eyes, 73 these leave on them only evanescent traces; scarcely sooner received than obliterated.

74 Corrupt people only attack the gods when they conceive them to be the enemies to their vile passions. 75 Arrian says, "that when people imagine the gods are in opposition to their passions, they abuse them, and overturn their altars." The Chinese, I believe, do the same. 76 The honest person makes war against systems which one finds are inimical to virtue-- injurious to own happiness-- baneful to that of own fellow mortals-- contradictory to the repose, fatal to the interests of the human species. 77 The bolder, therefore, the sentiments of the honest atheist, the more strange your ideas, the more

suspicious they appear to other people, the more strictly you ought to observe your own obligations; 78 the more scrupulously you should perform your duties; especially if you be not desirous that your morals shall calumniate your system; 79 which duly weighed, will make the necessity of sound ethics, the certitude of morality, felt in all its force; but which every species of superstition tends to render problematical, or to corrupt.

80 Whenever our will is moved by concealed and complicated motives, it is extremely difficult to decide what determines it; 81 a wicked person may be conducted to incredulity or to scepticism by those motives which you dare not avow, even to yourself; 82 in believing you seeks after truth, you may form an illusion to your mind, only to follow the interest of your passions; 83 the fear of an avenging system will perhaps determine you to deny their existence without examination; uniformly because you feels them incommodious.

84 Nevertheless, the passions sometimes happen to be just; a great interest carries us on to examine things more minutely; 85 it may frequently make a discovery of the truth, even to you who seeks after it the least, or who is only desirous to be lulled to sleep, who is only solicitous to deceive yourself. 86 It is the same with a perverse person who stumbles upon truth, as it is with you, who flying from an imaginary danger, should encounter in your road a dangerous serpent, which in your haste you should destroy; 87 you does that by accident, without design, which a person, less disturbed in own mind, would have done with premeditated deliberation.

88 To judge properly of things, it is necessary to be disinterested; it is requisite to have an enlightened mind, to have connected ideas to compass a great system. 89 It belongs, in fact, only to the honest person to examine the proofs of systems-- to scrutinise the principles

of superstition; 90 it belongs only to the person acquainted with Nature, conversant with Her ways, to embrace with intelligence the cause of the SYSTEM OF NATURE. 91 The wicked are incapable of judging with temper; the ignorant are inadequate to reason with accuracy; the honest, the virtuous, are alone competent judges in so weighty an affair. 92 What do I say? Is not the virtuous person, from thence in a condition to ardently desire the existence of a system that remunerates the goodness of people?

93 If you renounces those advantages, which your virtue confers upon you the right to hope, it is, undoubtedly, because you finds them imaginary. 94 Indeed, every person who reflects will quickly perceive, that for one timid mortal, of whom these systems restrain the feeble passions, there are millions whose voice they cannot curb, of whom, on the contrary, they excite the fury; 95 for one that they console, there are millions whom they affright, whom they afflict; whom they make unhappy: 96 in short, you finds, that against one inconsistent enthusiast, which these systems, which are thought so excellent, render happy, they carry discord, carnage, wretchedness into vast countries; plunge whole nations into misery; deluge them with tears.

97 However this may be, do not let us inquire into motives which may determine a person to embrace a system; 98 let us rather examine the system itself; let us convince ourselves of its rectitude; 99 if we shall find that it is founded upon truth, we shall never be able to esteem it dangerous. 100 It is always falsehood that is injurious to human; if error be visibly the source of your sorrows, reason is the true remedy for them; this is the panacea that can alone carry consolation to your afflictions.

101 Do not let us farther examine the conduct of a person who presents us with a system; your ideas, as we have already said, may be extremely sound, when even your actions are highly deserving of censure. 102 If the system of atheism cannot make

you perverse, who is not so by your temperament, it cannot render you good, who does not otherwise know the motives that should conduct you to virtue. 103 At least we have proved, that the superstitious person, when you have strong passions, when you possesses a depraved heart, finds even in your creed a thousand pretexts more than the atheist, for injuring the human species.

104 The atheist has not, at least, the mantle of zeal to cover own vengeance; you have not the command of your priest to palliate your transports; you have not the glory of your gods to countenance your fury; 105 the atheist does not enjoy the faculty of expiating, at the expense of a sum of money, the transgressions of own life; of availing the self of certain ceremonies, by the aid of which you may atone for the outrages you may have committed against society; 106 you have not the advantage of being able to reconcile yourself with heaven, by some easy custom; to quiet the remorse of your disturbed conscience, by an attention to outward forms: 107 if crime has not deadened every feeling of your heart, you are obliged continually to carry within yourself an inexorable judge, who unceasingly reproaches you for your odious conduct; 108 who forces you to blush for your own folly; who compels you to hate yourself; who imperiously obliges you to fear examination, to dread the resentment of others.

109 The superstitious person, if you be wicked, gives yourself up to crime, which is followed by remorse; but your superstition quickly furnishes you with the means a getting rid of it; 110 your life is generally no more than a long series of error and grief, of sin and expiation, following each other in alternate succession; 111 still more, you frequently, as we have seen, perpetrates crimes of greater magnitude, in order to wash away the first. 112 Destitute of any permanent ideas on morality, you accustoms yourself to look upon nothing as criminal, but that which the ministers, the official expounders of

your system, forbid you to commit: 113 you considers actions of the blackest dye as virtues, or as the means of effacing those transgressions, which are frequently held out to you as faithfully executing the duties of your creed. 114 It is thus we have seen fanatics expiate their adulteries by the most atrocious persecutions; cleanse their souls from infamy by the most unrelenting cruelty; make atonement for unjust wars by the foulest means; qualify their usurpations by outraging every principle of virtue; 115 in order to wash away their iniquities, bathe themselves in the blood of those superstitious victims, whose infatuation made them martyrs.

116 An atheist, as you are falsely called, if you have reasoned justly, if you have consulted Nature, hath principles more determinate, more humane, than the superstitious; 117 your system, whether gloomy or enthusiastic, always conducts the latter either to folly or cruelty; 118 the imagination of the former will never be intoxicated to that degree, to make you believe that violence, injustice, persecution, or assassination are either virtuous or legitimate actions. 119 We every day see that superstition, or the cause of heaven, as it is called, hoodwinks even those people who on every other occasion are humane, equitable, and rational; 120 so much so, that they make it a paramount duty to treat with determined barbarity, those people who happen to step aside from their mode of thinking. 121 An heretic, an incredulous being, ceases to be a human, in the eyes of the superstitious. 122 Every society, infected with the venom of bigotry, offers innumerable examples of juridical assassination, which the tribunals commit without scruple, even without remorse. 123 Judges who are equitable on every other occasion, are no longer so when there is a question of theological opinions; 124 in steeping their hands in the blood of their victims, they believe, on the authority of the priests, they conform themselves to the views of the Divinity.

125 Almost every where the laws are subordinate to superstition; make themselves accomplices in its fanatical fury; 126 they legitimate those actions most opposed to the gentle voice of humanity; they even transform into imperative duties, the most barbarous cruelties. 127 The president Grammont relates, with a satisfaction truly worthy of a cannibal, the particulars of the punishment of Vanini, who was burned at Thoulouse, although he had disavowed the opinions with which he was accused; 128 this president carries his demoniac prejudices so far, as to find wickedness in the piercing cries, in the dreadful howlings, which torment wrested from this unhappy victim to superstitious vengeance. 129 Are not all these avengers of the gods miserable people, blinded by their piety, who, under the impression of duty, wantonly immolate at the shrine of superstition, those wretched victims whom the priests deliver over to them? 130 Are they not savage tyrants, who have the rank injustice to violate thought; who have the folly to believe they can enslave it? 131 Are they not delirious fanatics, on whom the law, dictated by the most inhuman prejudices, imposes the necessity of acting like ferocious brutes? 132 Are not all those sovereigns, who to gratify the vanity of the priesthood, torment and persecute their subjects, who sacrifice to their anthropophagite gods human victims, people whom superstitious zeal has converted into tigers? 133 Are not those priests, so careful of the soul's health, who insolently break into the sacred sanctuary of human's mind, to the end that they may find in your opinions motives for doing you an injury, 134 abominable knaves, disturbers of the public repose, whom superstition honours, but whom virtue detests?

135 What villains are more odious in the eyes of humanity, what depredators more hateful to the eye of reason, than those infamous inquisitors, 136 who by the blindness of princes, by the delirium of monarchs, enjoy the advantage of

passing judgment on their own enemies; who ruthlessly commit them to the charity of the flames? 137 Nevertheless, the fatuity of the people makes even these monsters respected; the favour of kings covers them with kindness; the mantle of superstitious opinion shields them from the effect of the just execration of every honest person. 138 Do not a thousand examples prove, that superstition has everywhere produced the most frightful ravages: that it has continually justified the most unaccountable horrors? 139 Has it not a thousand times armed its votaries with the dagger of the homicide; let loose passions much more terrible than those which it pretended to restrain; broken up the most sacred bonds by which mortals are connected with each other? 140 Has it not, under the pretext of duty, under the colour of faith, under the semblance of zeal, under the sacred name of piety, favoured cupidity, lent wings to ambition, countenanced cruelty, given a spring to tyranny? 141 Has it not legitimatised murder; given a system to perfidy; organised rebellion; made a virtue of regicide? 142 Have not those princes who have been foremost as the avengers of heaven, who have been the lictors of superstition, frequently themselves become its victims? 143 In short, has it not been the signal for the most dismal follies, the most wicked outrages, the most horrible massacres? 144 Has not its altars been drenched with human gore? 145 Under whatever form it has been exhibited, has it not always been the ostensible cause of the most bare-faced violation-- of the sacred rights of humanity?

146 Never will an atheist, as you are proper senses, persuade yourself that similar actions can be justifiable; never will you believe that you who commits them can be an estimable person; 147 there is no one but the superstitious, whose blindness makes you forget the most evident principles of morality, whose callous soul renders you deaf to the voice of Nature, whose zeal causes you to overlook the dictates of reason,

148 who can by any possibility imagine the most destructive crimes are the most prominent features of virtue. 149 If the atheist be perverse, they, at least, knows that they acts wrong; neither these systems, nor their priests, will be able to persuade them that they does right: 150 one thing, however, is certain, whatever crimes you may allow yourself to commit, you will never be capable of exceeding those which superstition perpetrates without scruple; 151 that it encourages in those whom it intoxicates with its fury; to whom it frequently holds forth wickedness itself, either as expiations for offences, or else as orthodox, meritorious actions.

152 Thus the atheist, however wicked you may be supposed, will at most be upon a level with the devotee, whose superstition encourages you to commit crimes, which it transforms into virtue. 153 As to conduct, if you be debauched, voluptuous, intemperate, adulterous, the atheist in this differs in nothing from the most credulously superstitious, who frequently knows how to connect these vices with your credulity, 154 to blend with your superstition certain atrocities, for which your priests, provided you renders due homage to their power, especially if you augments their exchequer, will always find means to pardon you. 155 If you be in Hindoostan, you brahmins will wash you in the sacred waters of the Ganges, while reciting a prayer. 156 If you be a Jew, upon making an offering, your sins will be effaced. 157 If you be in Japan, you will be cleansed by performing a pilgrimage. 158 If you be a Mahometan, you will be reputed a saint, for having visited the tomb of your prophet; 159 the Roman pontiff himself will sell you indulgences; but none of them will ever censure you for those crimes you may have committed in the support of their several faiths.

160 We are constantly told, that the indecent behaviour of the official expounders of superstition, the criminal conduct of the priests, or of their sectaries, proves nothing against the goodness of their systems. 161 Admitted: but wherefore do they not say the same thing of the conduct of those whom they call atheists, who, as we have already proved, may have a very substantive, a very correct system of morality, even while leading a very dissolute life? 162 If it be necessary to judge the opinions of humankind according to their conduct, which is the theory that would bear the scrutiny? Let us, then, examine the opinion of the atheist, without approving their conduct; 163 let us adopt your mode of thinking, if we find it marked by the truth; if it shall appear useful; if it shall be proved rational; but let us reject your mode of action, if that should be found blameable. 164 At the sight of a work performed with truth, we do not embarrass ourselves with the morals of the workman: 165 of what importance is it to the universe, whether the illustrious Newton was a sober, discreet citizen, or a debauched intemperate man? 166 It only remains for us to examine your theory; we want nothing more than to know whether you have reasoned acutely; if your principles be steady; if the parts of your system are connected; if your work contains more demonstrable truths, than bold ideas? 167 Let us judge in the same manner of the principles of the atheist; if they appear strange, if they are unusual, that is a solid reason for probing them more strictly; 168 if you have spoken truth, if you have demonstrated your positions, let us yield to the weight of evidence; 169 if you be deceived in some parts, let us distinguish the true from the false; but do not let us fall into the hackneyed prejudice, which on account of one error in the detail, rejects a multitude of incontestable truisms. 170 Doctor Johnson, I think, says in his preface to his Dictionary, "when a man shall have executed his task with all the accuracy possible, he will only be allowed to have done his duty; but if he commits the

slightest error, a thousand snarlers are ready to point it out."

171 The atheist, when you are deceived, has unquestionably as much right to throw your faults on the fragility of your nature, as the superstitious person. 172 An atheist may have vices, may be defective, you may reason badly; but your errors will never have the consequences of superstitious novelties;173 they will not, like these, kindle up the fire of discord in the bosom of nations; 174 the atheist will not justify own vices, defend own wanderings by superstition; 175 you will not pretend to infallibility, like those self-conceited theologians who attach the Divine sanction to their follies; 176 who initiate that heaven authourise those sophisms, gives currency to those falsehoods, approves those errors, which they believe themselves warranted to distribute over the face of the earth. 177 It will perhaps be said, that the refusal to believe in these systems, will rend asunder one of the most powerful bonds of society, by making the sacredness of an oath vanish. 178 I reply, that perjury is by no means rare, even in the most superstitious nations, nor even among the most religious, or among those who boast of being the most thoroughly convinced of the rectitude of their theories.

179 Diagoras, superstitious as he was, and it was not well possible to be more so, it is said became an atheist, on seeing that the gods did not thunder their vengeance on a person who had taken them as evidence to a falsity. 180 Upon this principle, how many atheists ought there to be? 181 From the systems that have made invisible unknown beings the depositories of human's engagements, we do not always see it result that they are better observed; or that the most solemn contracts have acquired a greater solidity. 182 If history was consulted, it would now and then be in evidence, that even the conductors of nations, those who have said they were the images of the Divinity, 183 who have declared that they held their right of governing immediately from His hands, have sometimes taken the

Deity as the witness to their oaths, 184 have made Him the guarantee of their treaties, without its having had all the effect that might have been expected, when very trifling interests have intervened; 185 it would appear, unless historians are incorrect, that they did not always religiously observe those sacred engagements they made with their allies, much less with their subjects.

186 To form a judgment from these historic documents, we should be inclined to say, there have been those who had much superstition, joined with very little probity; 187 who made a mockery both of gods and humans; who perhaps blushed when they reviewed their own conduct: 188 nor can this be at all surprising, when it not infrequently happened that superstition itself absolved them from their oaths. 189 In fact, does not superstition sometimes inculcate perfidy; prescribe violation of plighted faith? 190 Above all, when there is a question of its own interests, does it not dispense with engagements, however solemn, made with those whom it condemns? 191 It is, I believe, a maxim in the Romish church, that "no faith is to be held with heretics." 192 The general council of Constance decided thus, when, notwithstanding the emperor's passport, it decreed John Hus and Jerome of Prague to be burnt. 193 The Roman pontiff has, it is well known, the right of relieving their sectaries from their oaths; of annulling their vows: 194 this same pontiff has frequently arrogated to the self the right of deposing kings; of absolving their subjects from their oaths of fidelity. 195 Indeed, it is rather extraordinary that oaths should be prescribed, by the laws of those nations which profess Christianity, seeing that Christ has expressly forbidden the use of them.

196 If things were considered attentively, it would be obvious that under such management, superstition and politics are schools of perjury. 197 They render it common: thus knaves of every description never recoil, when it is necessary to attest the name of the Divinity to the most manifest frauds, for the vilest interests. 198 What end, then, do

oaths answer? They are snares, in which simplicity alone can suffer itself to be caught: 199 oaths, almost everywhere, are vain formalities, that impose nothing upon villains; 200 nor do they add anything to the sacredness of the engagements of honest people; who would neither have the temerity nor the wish to violate them; who would not think themselves less bound without an oath. 201 A perfidious, perjured, superstitious being, has not any advantage over an atheist, who should fail in own promises: 202 neither the one nor the other any longer deserves the confidence of their fellow citizens nor the esteem of good people; 203 if one does not respect own gods, in whom one believes, the other neither respects own reason, own reputation, nor public opinion, in which all rational people cannot refuse to believe.

204 Hobbes says, "an oath adds nothing to the obligation. For a covenant, if lawful, binds in the sight of God, without the oath, as much as with it: if unlawful, bindeth not at all: though it be confirmed with an oath." 205 The heathen form was, "let Jupiter kill me else, as I kill this beast." 206 Adjuration only augments, in the imagination of one who swears, the fear of violating an engagement, which he would have been obliged to keep, even without the ceremony of an oath.

207 It has frequently been asked, if there ever was a nation that had no idea of the Divinity: and if a people, uniformly composed of atheists, would be able to subsist? 208 Whatever some speculators may say, it does not appear likely that there ever has been upon our globe, a numerous people who have not had an idea of some invisible power, to whom they have shown marks of respect and submission: 209 it has been sometimes believed that the Chinese were atheists: but this is an error, due to the Christian missionaries, who are accustomed to treat all those as atheists, who do not hold opinions similar with their own upon Divinity. 210 It always appears that the Chinese are a

people extremely addicted to superstition, but that they are governed by chiefs who are not so, without however their being atheists for that reason. 211 If the empire of China be as flourishing as it is said to be, it at least furnishes a very forcible proof that those who govern have no occasion to be themselves superstitious, in order to govern with propriety a people who are so.

212 It is pretended that the Greenlanders have no idea of the Divinity. Nevertheless, it is difficult to believe it of a nation so savage. 213 Human, inasmuch as you are a fearful, ignorant animal, necessarily becomes superstitious in your misfortunes: 214 either you forms gods for yourself, or you admits the gods which others are disposed to give you; 215 it does not then appear, that we can rationally suppose there may have been, or that there actually is, a people on the earth a total stranger to some Divinity. 216 One will show us the sun, the moon, or the stars; the other will show us the sea, the lakes, the rivers, which furnish them their subsistence, the trees which afford them an asylum against the inclemency of the weather; 217 another will show us a rock of an odd form; a lofty mountain; or a volcano that frequently astonishes them by its emission of lava; 218 another will present you with their crocodile, whose malignity they fears; their dangerous serpent, the reptile to which they attributes their good or bad fortune. 219 In short, each individual will make you behold their phantasm or their tutelary or domestic gods with respect.

220 But from the existence of your gods, the savage does not draw the same inductions as the civilised, polished person: the savage does not believe it a duty to reason continually upon their qualities; 221 you does not imagine that they ought to influence your morals, nor entirely occupy your thoughts: 222 content with a gross, simple, exterior worship, you does not believe that

these invisible powers trouble themselves with your conduct towards your fellow creatures; in short, you does not connect your morality with your superstition. 223 This morality is coarse, as must be that of all ignorant people; it is proportioned to your wants, which are few; it is frequently irrational, because it is the fruit of ignorance; of inexperience; of the passions of humans but slightly restrained, or to say thus, in their infancy. 224 It is only numerous, stationary, civilised societies, where human's wants are multiplied, where your interests clash, that you are obliged to have recourse to government, to laws, to public worship, in order to maintain concord. 225 It is then, that people approximating reason together, combine their ideas, refine their notions, subtilise their theories; 226 it is then also, that those who govern them avail themselves of invisible powers, to keep them within bounds, to render them docile, to enforce their obedience, to oblige them to live peaceably.

227 It was thus, that by degrees, morals and politics found themselves associated with superstitious systems. 228 The chiefs of nations, frequently, themselves, the children of superstition, but little enlightened upon their actual interests; slenderly versed in sound morality; 229 with an extreme exilty of knowledge on the actuating motives of the human heart; believed they had effected everything requisite for the stability of their own authority; 230 as well as achieved all that could guarantee the repose of society, that could consolidate the happiness of the people, in rendering their subjects superstitious like themselves; 231 by menacing them with the wrath of invisible powers; in treating them like infants who are appeased with fables, like children who are terrified by shadows. 232 By the assistance of these marvellous inventions, to which even the chiefs, the conductors of nations, are themselves frequently the dupes; which are transmitted as heirlooms from race to race; 233 sovereigns were dispensed from the trouble of instructing

themselves in their duties; they in consequence neglected the laws, enervated themselves in luxurious ease, rusted in sloth; followed nothing but their caprice: 234 the care of restraining their subjects was reposed in their deities; the instruction of the people was confided to their priests, 235 who were commissioned to train them to obedience, to make them submissive, to render them devout, to teach them at an early age to tremble under the yoke of both the visible and invisible gods.

236 It was thus that nations, kept by their tutors in a perpetual state of infancy, were only restrained by vain, chimerical theories. 237 It was thus that politics, jurisprudence, education, morality, were almost everywhere infected with superstition; that person no longer knew any duties, save those which grew out of its precepts: 238 the ideas of virtue were thus falsely associated with those of imaginary systems, to which imposture generally gave that language which was most conducive to its own immediate interests: 239 humankind thus fully persuaded, that without these marvellous systems, there could not exist any sound morality, 240 princes, as well as subjects, equally blind to their actual interests, to the duties of Nature, to their reciprocal rights, habituated themselves to consider superstition as necessary to mortals-- 241 as indispensably requisite to govern humans-- as the most effectual method of preserving power-- as the most certain means of attaining happiness.

242 It is from these dispositions, of which we have so frequently demonstrated the fallacy, that so many people, otherwise extremely enlightened, look upon it as an impossibility that a society formed of atheists, as they are termed, could subsist for any length of time. 243 It does not admit a question, that a numerous society, who should neither have religion, morality, government, laws, education, nor

principles, could not maintain itself; 244 that it would simply congregate beings disposed to injure each other, or children who would follow nothing but the blindest impulse; 245 but then is it not a lamentable fact, that with all the superstition that floats in the world, the greater number of human societies are nearly in this state? 246 Are not the sovereigns of almost every country in a continual state of warfare with their subjects? 247 Are not the people, in despite of their superstition, notwithstanding the terrific notions which it holds forth, unceasingly occupied with reciprocally injuring each other; with rendering themselves mutually unhappy? 248 Does not superstition itself, with its supernatural notions, unremittingly flatter the vanity of monarchs, unbridle the passions of princes, throw oil into the fire of discord, which it kindles between those citizens who are divided in their opinion? 249 Could those infernal powers, who are supposed to be ever on the alert to mischief humankind, be capable of inflicting greater evils upon the human race than spring from fanaticism, than arise out of the fury to which theology gives birth? 250 Could atheists, however irrational they may be supposed, if assembled together in society, conduct themselves in a more criminal manner? 251 In short, is it possible they could act worse than the superstitious, who, saturated with the most pernicious vices, guided by the most extravagant systems, during so many successive ages, have done nothing more than torment themselves with the most cruel inflictions; 252 savagely cut each other's throats, without a shadow of reason; make a merit of mutual extermination? It cannot be pretended they would. 253 On the contrary, we boldly assert, that a community of atheists, as the theologian calls them, because they cannot fall in with own mysteries, destitute of all superstition, governed by wholesome laws, formed by a salutary education, 254 invited to the practice of virtue by instantaneous recompences, deterred from crime by immediate punishments,

disentangled from illusive theories, unsophisticated by falsehood, 255 would be decidedly more honest, incalculably more virtuous, than those superstitious societies, in which everything contributes to intoxicate the mind; where everything conspires to corrupt the heart.

256 When we shall be disposed usefully to occupy ourselves with the happiness of humankind, it is with superstition that the reform must commence; 257 it is by abstracting these imaginary theories, destined to affright the ignorant, who are completely in a state of infancy, that we shall be able to promise ourselves the desirable harvest of conducting human to a state of maturity. 258 It cannot be too often repeated, there can be no morality without consulting the nature of human, without studying your actual relations with the beings of your own species; 259 there can be no fixed principle for human's conduct, while it is regulated upon unjust theories; upon capricious doctrines; upon corrupt systems; 260 there can be no sound politics without attending to human temperament, without contemplating you as a being associated for the purpose of satisfying your wants, consolidating your happiness, and assuring its enjoyment.

261 No wise government can found itself upon despotic systems; they will always make tyrants of their representatives. 262 No laws can be wholesome, that do not bottom themselves upon the strictest equity; which have not for their object the great end of human society. 263 No jurisprudence can be advantageous for nations, if its administration be regulated by capricious systems, or by human passions deified. 264 No education can be salutary, unless it be founded upon reason; to be efficacious to its proposed end, it must neither be construed upon chimerical theories, nor upon received prejudices. 265 In short, there can be no probity, no talents, no virtue, either under corrupt masters, or under the conduct of those priests who render human the enemy to the self--the determined foe

to others; 266 who seek to stifle in your bosom the germ of reason; who endeavour to smother science, or who try to damp your courage.

267 It will, perhaps, be asked, if we can reasonably flatter ourselves with ever reaching the point to make a whole people entirely forget their superstitious opinions; or abandon the ideas which they have of their gods? 268 I reply, that the thing appears utterly impossible; that this is not the end we can propose to ourselves. 269 These ideas, inculcated from the earliest ages, do not appear of a nature to admit eradication from the mind of the majority of humankind: 270 it would, perhaps be equally arduous to give them to those people, who, arrived at a certain time of life, should never have heard them spoken of, as to banish them from the minds of those, who have been imbued with them from their tenderest infancy. 271 Thus, it cannot be reckoned possible to make a whole nation pass from the abyss of superstition, that is to say, from the bosom of ignorance, from the ravings of delirium, into absolute naturalism, 272 or as the priests of superstition would denominate it, into atheism; which supposes reflection-- requires intense study-- demands extensive knowledge-- exacts a long series of experience-- includes the habit of contemplating Nature-- the faculty of observing Her laws; 273 which, in short, embraces the expansive science of the causes producing Her various phenomena; Her multiplied combinations, together with the diversified actions of the beings She contains, as well as their numerous properties.

274 In order to be an atheist, or to be assured of the capabilities of Nature, it is imperative to have meditated Her profoundly: 275 a superficial glance of the eye will not bring human acquainted with Her resources; optics but little practised on Her powers, will unceasingly be deceived; 276 the

ignorance of actual causes will always induce the supposition of those which are imaginary; 277 credulity will, thus re-conduct the natural philosopher to the feet of superstitious phantoms, in which either own limited vision, or own habitual sloth, will make believe the self shall find the solution to every difficulty.

278 Atheism, then, as well as philosophy, like all profound abstruse sciences, is not calculated for the vulgar; neither is it suitable to the great mass of humankind. 279 There are, in all populous, civilised nations, people whose circumstances enable them to devote their time to meditation, 280 whose easy finances afford them leisure to make deep researches into the nature of things, 281 who frequently make useful discoveries, which, sooner or later, after they have been submitted to the infallible test of experience, 282 when they have passed the fiery ordeal of truth, extend widely their salutary effects, become extremely beneficial to society, highly advantageous to individuals. 283 The geometrician, the chemist, the mechanic, the natural philosopher, the civilian, the artisan, are industriously employed, either in their closets, or in their workshops, seeking the means to serve society, each in own sphere: 284 nevertheless, not one of their sciences or professions are familiar to the illiterate; not one of the arts with which they are respectively occupied, are known to the uninitiated: 285 these, however, do not fail, in the long run, to profit by them, to reap substantive advantages from those labour, of which they themselves have no idea. 286 It is for the mariner, that the astronomer explores own arduous science; it is for the mariner the geometrician calculates; for their use the mechanic plies own craft: 287 it is for the mason, for the carpenter, for the labourer, that the skillful architect studies own orders, lays down well-proportioned elaborate plans.

288 Whatever may be the pretended utility of Pneumatology, whatever may be the vaunted advantages of superstitious opinions, the wrangling polemic, the subtle theologian,

cannot boast either of toiling, of writing, or of disputing for the advantage of the people, 289 whom, notwithstanding, they contrives to tax, very exorbitantly, for those systems they can never understand; 290 from whom they levies the most oppressive contributions, as a remuneration for the detail of those mysteries, which under any possible circumstances, cannot, at any time whatever, be of the slightest benefit to them. 291 It is not, then, for the multitude that a philosopher should propose to the self, either to write or to meditate: 292 the Code of Nature, or the principles of atheism, as the priest calls it, are not, as we have shown, even calculated for the meridian of a great number of people, 293 who are frequently too much prepossessed in favour of the received prejudices, although extremely enlightened on other points. 294 It is extremely rare to find people, who, to an enlarged mind, extensive knowledge, great talents, join either a well regulated imagination, or the courage necessary to successfully oppugn habitual errors; 295 triumphantly to attack those chimerical systems, with which the brain has been inoculated from the first hour of its birth.

296 A secret bias, an invincible inclination, frequently, in despite of all reasoning, re-conducts the most comprehensive, the best fortified, the most liberal minds, to those prejudices which have a wide-spreading establishment; 297 of which they have themselves taken copious draughts during the early stages of life. 298 Nevertheless, those principles, which at first appear strange, which by their boldness seem revolting, from which timidity flies with trepidation, when they have the sanction of truth, gradually insinuate themselves into the human mind, 299 become familiar to its exercise, extend their happy influence on every side, and finally produce the most substantive advantages to society. 300 In time, people habituate themselves to ideas which originally they looked

upon as absurd; which on a superficial glance they contemplated as either noxious or irrational: 301 at least, they cease to consider those as odious, who profess opinions upon subjects on which experience makes it evident they may be permitted to have doubts, without imminent danger to public tranquillity.

302 Then the diffusion of ideas among humankind is not an event to be dreaded: if they are truths, they will of necessity be useful: by degrees they will fructify. 303 The person who writes, must neither fix own eyes upon the time in which you lives, upon your actual fellow citizens, nor upon the country you inhabits. 304 You must speak to the human race; you must instruct future generations; you must extend your views into the bosom of futurity; 305 in vain you will expect the eulogies of your contemporaries; in vain will you flatter yourself with seeing your reasoning adopted; 306 in vain you will soothe yourself with the pleasing reflection, that your precocious principles will be received with kindness; 307 if you have exhibited truisms, the ages that shall follow will do justice to your efforts; unborn nations shall applaud your exertions; 308 your future country-people shall crown your sturdy attempts with those laurels, which interested prejudice withholds from you in your own days; 309 it must therefore be from posterity, you are to expect the need of applause due to your services; 310 the present race is hermetically sealed against you: meantime let you content yourself with having done well; with the secret suffrages of those few friends to veracity who are so thinly spread over the surface of the earth. 311 It is after your death, that the trusty reasoner, the faithful writer, the promulgator of sterling principles, the child of simplicity, triumphs; 312 it is then that the stings of hatred, the shafts of

envy, the arrows of malice, either exhausted or blunted, enable humankind to judge with impartiality; 313 to yield to conviction; to establish eternal truth upon its own imperishable altars, which from its essence must survive all the error of the earth. 314 It is then that calumny, crushed like the devouring snail by the careful gardener, ceases to besmear the character of an honest person, 315 while its venomous slime, glazed by the sun, enables the observant spectator to trace the filthy progress it had made.

316 It is a problem with many people, if truth may not be injurious? The best intentioned people are frequently in great doubt upon this important point. 317 The fact is, it never injures any but those who deceive humankind: this has, however, the greatest interest in being undeceived. 318 Truth may be injurious to the individual who announces it, but it can never by any possibility harm the human species; 319 never can it be too distinctly presented to beings, always either little disposed to listen to its dictates, or too slothful to comprehend its efficacy. 320 If all those who write to publish important truths, which, of all others, are ever considered the most dangerous, were sufficiently ardent for the public welfare to speak freely, even at the risk of displeasing their readers, the human race would be much more enlightened, much happier than it now is. 321 To write in ambiguous terms, is very frequently to write to nobody. 322 The human mind is idle; we must spare it, as much as possible, the trouble of reflection; we must relieve it from the embarrassment of intense thinking. 323 What time does it not consume, what study does it not require, at the present day, to unravel the amphibological oracles of the ancient philosophers, whose actual sentiments are almost entirely lost to the present race of humans?

324 If truth be useful to human beings, it is an injustice to deprive them of its advantages; 325 if truth ought to be admitted, we must admit its consequences, which are also

truths. 326 Human, taken generally, is fond of truth, but its consequences often inspire you with so much dread, so alarm your imbecility, 327 that, frequently, you prefers remaining in error, of which a confirmed habit prevents you from feeling the deplorable effects. 328 Besides, we shall say with Hobbes, "that we cannot do people any harm by proposing truth to them; the worst mode is to leave them in doubt, to let them remain in dispute." 329 If an author who writes be deceived, it is because the author may have reasoned badly. 330 Have you laid down false principles? It remains to examine them. Is your system fallacious? Is it ridiculous? It will serve to make truth appear with the greatest splendour: 331 your work will fall into contempt; the writer, if you be witness to its fall, will be sufficiently punished for own temerity; if you be defunct, the living cannot disturb your ashes.

332 No person writes with a design to injure own fellow creatures; you always proposes to yourself to merit their suffrages, either by amusing them, by exciting their curiosity, or by communicating to them discoveries, which you believes useful. 333 Above all, no work can be really dangerous, if it contains truth. 334 It would not be so, even if it contained principles evidently contrary to experience-- opposed to good sense. 335 Indeed, what would result from a work that should now tell us the sun is not luminous; that parricide is legitimate; that robbery is allowable; that adultery is not a crime? 336 The smallest reflection would make us feel the falsity of these principles; the whole human race would protest against them. 337 People would laugh at the folly of the author; presently the book, together with own name, would be known only by its ridiculous extravagances. 338 There is nothing but superstitious follies that are pernicious to mortals; and wherefore? It is because authority always pretends to establish them by violence; to make them pass for substantive virtues; 339 rigorously punishes those who shall be disposed

to smile at their inconsistency, or examine into their pretensions.

340 If human was more rational, you would examine superstitious opinions as you examines everything else; 341 you would look upon theological theories with the same eyes that you contemplates systems of natural philosophy, or problems in geometry: 342 the latter never disturbs the repose of society, although they sometimes excite very warm disputes in the learned world. 343 Theological quarrels would never be attended with any evil consequences, if human could gain the desirable point of making those who exercise power, feel that the disputes of people, 344 who do not themselves understand the marvellous questions upon which they never cease wrangling, ought not to give birth to any other sensations than those of indifference; to rouse no other passion than that of contempt.

345 It is, at least, this indifference not speculative theories, so just, so rational, so advantageous for states, that sound philosophy may propose to introduce, gradually, upon the earth. 346 Would not the human race be much happier-- if the sovereigns of the world, occupied with the welfare of their subjects, leaving to superstitious theologians their futile contests, making their various systems yield to healthy politics; 347 obliged these haughty ministers to become citizens; carefully prevented their disputes from interrupting the public tranquillity? 348 What advantage might there not result to science; what a start would be given to the progress of the human mind, to the cause of sound morality, 349 to the advancement of equitable jurisprudence, to the improvement of legislation, to the diffusion of education, from an unlimited freedom of thought?

350 At present, genius everywhere finds trammels; superstition invariably opposes itself to its course; 351 human, straitened with bandages, scarcely enjoys the free use of any one of own faculties; 352 your mind itself is cramped; it appears continually wrapped up in the swaddling clothes of infancy. 353

NATURE

The civil power, leagued with spiritual domination, appears only disposed to rule over brutalised slaves, shut up in a dark prison, where they reciprocally goad each other with the effervescence of their mutual ill-humour. 354 Sovereigns, in general, detest liberty of thought, because they fear truth; this appears formidable to them, because it would condemn their excesses; 355 these irregularities are dear to them, because they do not, better than their subjects, understand their true interests; properly considered these ought to blend themselves into one uniform mass.

356 Let not the courage of the philosopher, however, be abated by so many united obstacles, which would appear for ever to exclude truth from its proper dominion; to banish reason from the mind of human; to spoil Nature of Her imprescriptible rights. 357 The thousandth part of those cares which are bestowed to infect the human mind, would be amply sufficient to make it whole. 358 Let us not, then, despair of the case: do not let us do human the injury to believe that truth is not made for you; 359 your mind seeks after it incessantly; your heart desires it faithfully; your happiness demands it with an imperious voice; 360 you only either fears it, or mistakes it, because superstition, which has thrown all your ideas into confusion, perpetually keeps the bandeau of delusion fast bound over your eyes; strives, with an almost irresistible force, to render you an entire stranger to virtue.

361 Maugre the prodigious exertions that are made to drive truth from the earth; in spite of the extraordinary pains used to exile reason-- of the uninterrupted efforts to expel true science from the residence of mortals; 362 time, assisted by the progressive knowledge of ages, may one day be able to enlighten even those princes who are the most outrageous in their opposition to the illumination of the human mind; 363 who appear

such decided enemies to justice, so very determined against the liberties of humankind.

364 Destiny will, perhaps, when least expected, conduct these wandering outcasts to the throne of some enlightened, equitable, courageous, generous, benevolent sovereign, 365 who, smitten with the charms of virtue, shall throw aside duplicity, frankly acknowledge the true source of human misery, and apply to it those remedies with which wisdom has furnished him: 366 perhaps you may feel, that those systems, from whence it is pretended you derives your power, are the true scourges of your people; the actual cause of your own weakness: 367 that the official expounders of these systems are your most substantial enemies-- your most formidable rivals; 368 you may find that superstition, which you have been taught to look upon as the main support to your authority, in point of fact only enfeebles it-- renders it tottering: 369 that superstitious morality, false in its principles, is only calculated to pervert your subjects; to break down their intrepidity; to render them perfidious; in short, to give them the vices of slaves, in lieu of the virtues of citizens. 370 A prince thus disentangled from prejudice, will perhaps behold, in superstitious errors, the fruitful source of human sorrows, and commiserations, the condition of own race, it may be, will generously declare, that they are incompatible with every equitable administration.

371 Until this epoch, so desirable for humanity, shall arrive, the principles of naturalism will be adopted only by a small number of liberal-minded people, who shall dive below the surface; 372 these cannot flatter themselves either with making proselytes, or having a great number of approvers: 373 on the contrary, they will meet with zealous adversaries, with ardent condemners, even in those people who upon every other subject discover the most acute minds; display the most consummate

knowledge. 374 Those people who possess the greatest share of ability, as we have already observed, cannot always resolve to divorce themselves completely from their superstitious ideas; 375 imagination, so necessary to splendid talents, frequently forms in them an insurmountable obstacle to the total extinction of prejudice; this depends much more upon the judgment than upon the mind. 376 To this disposition, already so prompt to form illusions to them, is also to be joined the force of habit; 377 to a great number of people, it would be wresting from them a portion of themselves to take away their superstitious notions; 378 it would be depriving them of an accustomed aliment; plunging them into a dreadful vacuum: obliging their distempered minds to perish for want of exercise.

379 Menage remarks, "that history speaks of very few incredulous women, or female atheists:" 380 this is not surprising; their organisation renders them fearful; their nervous system undergoes periodical variations; the education they receive disposes them to credulity. 381 Those among them who have a sound constitution, who have a well ordered imagination, have occasion for chimeras suitable to occupy their leisure; 382 above all, when the world abandons them, then superstitious devotion, with its attractive ceremonies, becomes either a business or an amusement.

383 Let us not be surprised, if very intelligent, extremely learned people, either obstinately shut their eyes, or run counter to their ordinary sagacity, 384 every time there is a question respecting an object which they have not the courage to examine with that attention they lend to many others.

385 Lord Chancellor Bacon pretends, "that a little philosophy disposes people to atheism, but that great depth re-conducts them to religion." 386 If we analyses this proposition, we shall find it signifies, that even moderate, indifferent thinkers, are quickly enabled to perceive the gross absurdities of superstition; 387

but that very little accustomed to meditate, or else destitute of those fixed principles which could serve them for a guide, 388 their imagination presently replaces them in the theological labyrinth, from whence reason, too weak for the purpose, appeared disposed to withdraw them: 389 these timid souls, who fear to take courage, with minds disciplined to be satisfied with theological solutions, no longer see in Nature anything but an inexplicable enigma; an abyss which it is impossible for them to fathom: 390 these, habituated to fix their eyes upon an ideal, mathematical point, which they have made the centre of everything, whenever they lose sight of it, find the universe becomes an unintelligible jumble to them; 391 then the confusion in which they feel themselves involved, makes them rather prefer returning to the prejudices of their infancy, 392 which appear to explain everything, than to float in the vacuum, or quit a foundation which they judge to be immoveable. 393 Thus the proposition of Bacon should seem, to indicate nothing, except it be that the most experienced people cannot at all times defend themselves against the illusions of their imagination; the impetuosity of which resists the strongest reasoning.

394 Nevertheless, a deliberate study of Nature is sufficient to undeceive every human who will calmly consider things: 395 you will discover that the phenomena of the world is connected by links, invisible to superficial notice, equally concealed from the too impetuous observer, but extremely intelligible to you who views Her with serenity. 396 You will find that the most unusual, the most marvellous, as well as the most trifling, or ordinary effects, are equally inexplicable, but that they all equally flow from natural causes; 397 that supernatural causes, under whatever name they may be designated, with whatever

qualities they may be decorated, will never do more than increase difficulties; will only make chimeras multiply. 398 The simplest observation will incontestably prove to you that everything is necessary; that all the effects you perceives are material; 399 that they can only originate in causes of the same Nature, when you even shall not be able to recur to them by the assistance of your senses. 400 Thus your mind, properly directed, everywhere show you nothing but matter, sometimes acting in a manner which your organs permit you to follow, at others in a mode imperceptible by the faculties you possesses: 401 you will see that all beings follow constant invariable laws, by which all combinations are united and destroyed; 402 you will find that all forms change, but that, nevertheless, the great whole ever remains the same.

403 Thus, cured of the idle notions with which you was imbued, undeceived in those erroneous ideas, which from habit be attached to imaginary systems, you will cheerfully consent to be ignorant of whatever your organs do not enable you to compass; 404 you will know that obscure terms, devoid of sense, are not calculated to explain difficulties; 405 guided by reason, you will throw aside all hypothesis of the imagination; the champion of rectitude, you will attach yourself to realities, which are confirmed by experience, which are evidenced by truth.

406 The greater number of those who study Nature, frequently do not consider, that prejudiced eyes will never discover more than that which they have previously determined to find: 407 as soon as they perceive facts contrary to their own ideas, they quickly turn aside, and believe their visual organs have deceived them; 408 if they return to the task, it is in hopes to find means by which they may reconcile the facts to the notions with which their own

mind is previously tinctured. 409 Thus we find enthusiastic philosophers, whose determined prepossession shows them what they denominate incontestable evidences of the systems with which they are per-occupied, even in those things, that most openly contradict their hypothesis: 410 hence those pretended demonstrations of the existence of theories, which are drawn from final causes-- from the order of Nature-- from the kindness evinced to human.

411 Do these same enthusiasts perceive disorder, witness calamities? 412 They induct new proofs of the wisdom, fresh evidence of the intelligence, additional testimony to the bounty of their system, whilst all these occurrences as visibly contradict these qualities, as the first seem to confirm or to establish them. 413 These prejudiced observers are in an ecstasy at the sight of the periodical motions of the planets; at the order of the stars; at the various productions of the earth; at the astonishing harmony in the component parts of animals: 414 in that moment, however, they forget the laws of motion; the powers of gravitation; the force of attraction and repulsion; 415 they assign all these striking phenomena to unknown causes, of which they have no one substantive idea. 416 In short, in the fervour of their imagination they place human in the centre of Nature; they believe you to be the object, the end, of all that exists; 417 that it is for your convenience everything is made; that it is to rejoice your mind, to pleasure your senses, that the whole was created; 418 whilst they do not perceive, that very frequently the entire of Nature appears to be loosed against your weakness; that the elements themselves overwhelm you with calamity; that destiny obstinately persists in rendering you the most miserable of beings. 419 The progress of sound philosophy will always be fatal

to superstition, whose notions will be continually contradicted by Nature.

420 Astronomy has caused judiciary astrology to vanish; experimental philosophy, the study of natural history and chemistry, have rendered it impossible for jugglers, priests or sorcerers, any longer to perform miracles. 421 Nature, profoundly studied, must necessarily cause the overthrow of those chimerical theories, which ignorance has substituted to Her powers.

422 Atheism, as it is termed, is only so rare, because everything conspires to intoxicate human with a dazzling enthusiasm, from your most tender age; 423 to inflate you from your earliest infancy, with systematic error, with organised ignorance, which of all others is the most difficult to vanquish, the most arduous to root out. 424 Theology is nothing more than a science of words, which by dint of repetition we accustom ourselves to substitute for things: 425 as soon as we feel disposed to analyse them, we are astonished to find they do not present us with any actual sense.

426 There are, in the whole world, very few people who think deeply: who render to themselves a faithful account of their own ideas; who have keen penetrating minds. 427 Justness of intellect is one of the rarest gifts which Nature bestows on the human species. 428 It is not, however, to be understood by this, that Nature has any choice in the formation of Her beings; 429 it is merely to be considered, that the circumstances very rarely occur which enable the junction of a certain quantity of those atoms or parts, necessary to form the human machine in such due proportions, 430 that one disposition shall not overbalance the others; and thus render the judgment erroneous, by giving it a particular bias.

431 We know the general process of making gunpowder; nevertheless, it will sometimes happen that the ingredients have

been so happily blended, that this destructive article is of a superior quality to the general produce of the manufactory, 432 without, however, the chemist being on that account entitled to any particular commendation; circumstances have been decidedly favourable, and these seldom occur. 433 Too lively an imagination, an over eager curiosity, are as powerful obstacles to the discovery of truth, as too much phlegm, a slow conception, indolence of mind, or the want of a thinking habit: 434 all humans have more or less imagination, curiosity, phlegm, bile, indolence, activity: it is from the happy equilibrium which Nature has observed in their organisation, that depends that invaluable blessing, correctness of mind.

435 Nevertheless, as we have heretofore said, the organic structure of human is subject to change; the accuracy of your mind varies with the mutations of your machine: 436 from hence may be traced those almost perpetual revolutions that take place in the ideas of mortals; 437 above all when there is a question concerning those objects, upon which experience does not furnish any fixed basis whereon to rest their merits. 438 To search after right, to discover truth, requires a keen, penetrating, just, active mind; because everything strives to conceal from us its beauties: 439 it needs an upright heart, one in good faith with itself, joined to an imagination tempered with reason, because our habitual fears make us frequently dread its radiance, sometimes bursting like a meteor on our darkened faculties; 440 besides, it not infrequently happens, that we are actually the accomplices of those who lead us astray, by an inclination we too often manifest to dissimilate with ourselves on this important measure.

441 Truth never reveals itself either to the enthusiast smitten with own reveries; to the

mellifluous fanatic enslaved by your prejudices; to the vain glorious mortal puffed up with your presumptuous ignorance; to the voluptuary devoted to your pleasures; 442 or to the wily reasoner, who, disingenuous with yourself, has a peculiar spontaneity to form illusions to your mind. 443 Blessed, however, with a heart, gifted with a mind such as described, human will surely discover this ‘rara avis’: 444 thus constituted, the attentive philosopher, the geometrician, the moralist, the politician, the theologian, when you shall sincerely seek truth, will find that the corner-stone which serves for the foundation of all superstitious systems, is evidently rested upon fiction.

445 The philosopher will discover in matter a sufficient cause for its existence; they will perceive that its motion, its combination, its modes of acting, are always regulated by general laws, incapable of variation. 446 The geometrician, without quitting Nature, will calculate the active force of matter; it will then become obvious, that to explain its phenomena, it is by no means necessary to have recourse to that which is incommensurable with all known powers. 447 The politician, instructed in the true spring which can act upon the mind of nations, will feel distinctly, that it is not imperative to recur to imaginary theories, 448 whilst there are actual motives to give play to the volition of the citizens; to induce them to labour efficaciously to the maintenance of their association; 449 you will readily acknowledge that fictitious systems are calculated either to slaken the exertions, or to disturb the motion of so complicated a machine an human society.

450 You who shall more honour truth than the vain subtleties of theology, will quickly perceive that this pompous science is nothing more than an unintelligible jumble of false hypothesis; 451 that it continually

begs its principles; is full of sophisms; contains only vitiated circles; embraces the most subdolous distinctions; 452 is ushered to humankind by the most disingenuous arguments, from which it is not possible, under any given circumstances, there should result anything but puerilities-- the most endless disputes. 453 In short, all people who have sound ideas of morality, whose notions of virtue are correct, who understand what is useful to the human being in society, whether it be to conserve yourself individually, or the body of which you are a member, 454 will acknowledge, that in order to discover your relations, to ascertain your duties, you have only to consult your own nature; 455 that you ought to be particularly careful neither to found them upon discrepant systems, nor to borrow them from models that never can do more than disturb your mind; 456 that will only render your conduct fluctuating; that will leave you forever uncertain of its proper character.

457 Thus, every rational thinker, who renounces own prejudices, will be enabled to feel the inutility, to comprehend the fallacy of so many abstract systems; 458 you will perceive that they have hitherto answered no other purpose than to confound the notions of humankind; to render doubtful the clearest truths. 459 In quitting the regions of the empyreum, where your mind can only bewilder itself, in re-entering your proper sphere, in consulting reason, human will discover that of which you needs the knowledge; 460 you will be able to undeceive yourself upon those chimerical theories, which enthusiasm has substituted for actual natural causes; 461 to detect those figments, by which imposture has almost everywhere superseded the real motives that can give activity in Nature; 462 out of which the human mind never rambles, without going

woefully astray; without laying the foundation of future misery.

463 The Deicolists, as well as the theologians, continually reproach their adversaries with their taste for paradoxes-- with their attachment to systems; whilst they themselves found all their reasoning upon imaginary hypothesis-- upon visionary theories; 464 make a principle of submitting their understanding to the yoke of authority; of renouncing experience; of setting down as nothing the evidence of their senses. 465 Would it not be justifiable in the disciples of Nature, to say to these people, who thus despise Her, "We only assure ourselves of that which we see; we yield to nothing but evidence; if we have a system, it is one founded upon facts; 466 we perceive in ourselves, we behold everywhere else, nothing but matter; we therefore conclude from it that matter can both feel and think: we see that the motion of the universe is operated after mechanical laws; 467 that the whole results from the properties, is the effect of the combination, the immediate consequence of the modification of matter; 468 thus, we are content, we seek no other explication of the phenomena which Nature presents.

469 We conceive only an unique world, in which everything is connected; where each effect is linked to a natural cause, either known or unknown, which it produces according to necessary laws; 470 we affirm nothing that is not demonstrable; nothing that you are not obliged to admit as well as ourselves: 471 the principles we lay down are distinct: they are self-evident: they are facts. 472 If we find some things unintelligible, if causes frequently become arduous, we ingenuously agree to their obscurity; that is to say, to the limits of our own knowledge. 473 But in order to explain these effects, we do not imagine an hypothesis; we either consent to be for ever ignorant of them, or else we wait patiently until time, experience, with the progress of the human mind, shall throw them into light: 474 is not, then, our manner of philosophising consistent

with truth? Indeed, in whatever we advance upon the subject of Nature, we proceed precisely in the same manner as our opponents themselves pursue in all the other sciences, such as natural history, experimental philosophy, mathematics, chemistry. 475 We scrupulously confine ourselves to what comes to our knowledge through the medium of our senses; the only instruments with which Nature has furnished us to discover truth.

476 What is the conduct of our adversaries? In order to expound things of which they are ignorant, they imagine theories still more incomprehensible than what they are desirous to explain; 477 theories of which they themselves are obliged to acknowledge they have not the most slender notion. 478 Thus they invert the true principles of logic, which require we should proceed gradually from that which is most known, to that with which we are least acquainted. 479 Again, upon what do they found the existence of these theories, by whose aid they pretend to solve all difficulties? 480 It is upon the universal ignorance of humankind; upon the inexperience of human; upon your fears; upon your disordered imagination; upon a pretended intimate sense, which in reality is nothing more than the effect of vulgar prejudice; the result of dread; 481 the consequence of the want of a reflecting habit, which induces them to crouch to the opinions of others; to be guided by the mandates of authority, rather than take the trouble to examine for their own information.

482 Such, O theologians! are the ruinous foundations upon which you erect the superstructure of your doctrine. 483 Accordingly, you find it impossible to form to yourselves any distinct idea of those theories which serve for the basis of your systems; you are unable to comprehend either their attributes, their existence, the nature of their localities, or their mode of action. 484 Thus, even by your own confession, ye are in a state of profound ignorance, on the primary elements of that which ye constitute the cause of all that exists: 485 of which, according to your own

account, it is imperative to have a correct knowledge. 486 Under whatever point of view, therefore, ye are contemplated, it must be admitted ye are the founders of aerial systems; of fanciful theories: of all systematisers, ye are consequently the most absurd; 487 because in challenging your imagination to create a cause, this cause, at least, ought to diffuse light over the whole; 488 it would be upon this condition alone that its incomprehensibility could be pardonable; but to speak ingenuously, does this cause serve to explain anything? 489 Does it make us conceive more clearly the origin of the world; bring us more distinctly acquainted with the actual nature of human; 490 does it more intelligibly elucidate the faculties of the soul; or point out with more perspicuity the source of good and evil?

491 No! Unquestionably: these subtle theories explain nothing, although they multiply to infinity their own difficulties; they, in fact, embarrass elucidation, by plunging into greater obscurity those matters in which they are interposed. 492 Whatever may be the question agitated, it becomes complicated: as soon as these theories are introduced, they envelope the most demonstrable sciences with a thick, impenetrable mist; 493 render the most simple notions complex; give opacity to the most diaphanous ideas; turn the most evident opinions into insolvable enigmas.

494 What exposition of morality does the theories, upon which ye found all the virtue, present to human? Do not all your oracles breathe inconsistency? 495 Does not your doctrines embrace every gradation of character, however discrepant: every known property, however opposed. 496 All your ingenious systems, all your mysteries, all the subtilties which ye have invented, are they capable of reconciling that discordant assemblage of amiable and unamiable qualities, with which ye have dressed up your figments? 497 In short, is it not by these theories that ye disturb the harmony of the universe; is it not in their name ye follow up your barbarous proscriptions; 498 in their support,

that ye so inhumanly exterminate all who refuse to subscribe to your organised reveries; who withhold assent to those efforts of the imagination which ye have collectively decorated with the pompous name of religion; 499 but which, individually, ye brand as superstition, always excepting that to which ye lend yourselves.

500 Agree, then, O Theologians! Acknowledge, then, ye subtle metaphysicians! Consent, then, ye organisers of fanciful theories! that not only are ye systematically absurd, but also that ye finish by being atrocious; 501 because whenever ye obtain the ascendancy one over the other, your unfortunate pre-eminence is distinguished by the most malevolent persecution; 502 your domination is ushered in with cruelty; 503 your career is described with blood: from the importance which your own interest attaches to your ruinous dogmas; 504 from the pride with which ye tumble down the less fortunate systems of those who started with you for the prize of plunder; 505 from that savage ferocity, under which ye equally overwhelm human reason, the happiness of the individual, and the felicity of nations."

A SUMMARY OF THE CODE OF NATURE

Paul Henri Thiery (Baron D'Holbach)

57 Truth is the only object worthy the research of every wise person; since that which is false cannot be useful to you: whatever constantly injures you cannot be founded upon truth; consequently, ought to be forever proscribed. 2 It is, then, to assist the human mind, truly to labour for your happiness, to point out to you the clew by which you may extricate yourself from those frightful labyrinths in which your imagination wanders; 3 from those sinuosities whose devious course makes you err, without ever finding a termination to your incertitude. 4 Nature alone, known through experience, can furnish you with this desirable thread; Her eternal energies can alone supply the means of

attacking the Minotaur; of exterminating the figments of hypocrisy; 5 of destroying those monsters, who during so many ages, have devoured the unhappy victims, which the tyranny of the ministers of Moloch have exacted as a cruel tribute from affrighted mortals. 6 By steadily grasping this inestimable clew, rendered still more precious by the beauty of the donor, human can never be led astray-- will never ramble out of your course; 7 but if, careless of its invaluable properties, for a single instant you suffers it to drop from your hand; if, like another Theseus, ungrateful for the favour, you abandons the fair bestower, you will infallibly fall again into your ancient wanderings; 8 most assuredly become the prey to the cannibal offspring of the White Bull.

9 In vain shall you carry your views above your head, to find resources which are at your feet; 10 so long as human, infatuated with your superstitious notions, shall seek in an imaginary world the rule of your earthly conduct, you will be without principles; 11 while you shall pertinaciously contemplate the regions of a distempered fancy, so long you will grope in those where you actually finds yourself; 12 your uncertain steps will never encounter the welfare you desires; never lead you to that repose after which you so ardently sighs, nor conduct you to that surety which is so decidedly requisite to consolidate your happiness.

13 But human, blinded by your prejudices; rendered obstinate in injuring your fellow, by your enthusiasm; ranges yourself in hostility even against those who are sincerely desirous of procuring for you the most substantive benefits. 14 Accustomed to be deceived, you are in a state of continual suspicion; habituated to mistrust yourself, to view your reason with diffidence, to look upon truth as dangerous, you treats as enemies even those who most eagerly strive to encourage you; 15 forewarned in early life against delusion, by the subtilty of imposture, you believes

yourself imperatively called upon to guard with the most sedulous activity the bandeau with which they have hoodwinked you; 16 you thinks your eternal welfare involved in keeping it forever over your eyes; you therefore wrestles with all those who attempt to tear it from your obscured optics. 17 If your visual organs, accustomed to darkness, are for a moment opened, the light offends them; you are distressed by its effulgence; you thinks it criminal to be enlightened; you darts with fury upon those who hold the flambeau by which you are dazzled.

18 In consequence, the atheist, as the arch rogue from whom you differs ludicrously calls you, is looked upon as a malignant pest, as a public poison, which like another Upas, destroys everything within the vortex of its influence; 19 you who dares to arouse mortals from the lethargic habit which the narcotic doses administered by the theologians have induced passes for a perturbator; 20 you who attempts to calm their frantic transports, to moderate the fury of their maniacal paroxysms, is yourself viewed as a mad-person, who ought to be closely chained down in the dungeons appropriated to lunatics; 21 you who invites your associates to rend their chains asunder, to break their galling fetters, appears only like an irrational, inconsiderate being, even to the wretched captives themselves: 22 who have been taught to believe that Nature formed them for no other purpose than to tremble: only called them into existence that they might be loaded with shackles. 23 In consequence of these fatal prepossessions, the Disciple of Nature is generally treated as an assassin; 24 is commonly received by own fellow citizens in the same manner as the feathered race receive the doleful bird of night, which as soon as it quits its retreat, all the other birds follow

with a common hatred, uttering a variety of doleful cries.
25 No, mortals blended by terror! The friend of Nature is not your enemy; its interpreter is not the minister of falsehood; the destroyer of your vain phantoms is not the devastator of those truths necessary to your happiness; 26 the disciple of reason is not an irrational being, who either seeks to poison you, or to infect you with a dangerous delirium.
27 If you are desirous to wrest the thunder from those terrible theories that affright ye, it is that ye may discontinue your march, in the midst of storms, over roads that ye can only distinguish by the sudden, but evanescent glimmerings of the electric fluid. 28 If you breaks those idols, which fear has served with myrrh and frankencense-- which superstition has surrounded by gloomy despondency-- which fanaticism has imbrued with blood; 29 it is to substitute in their place those consoling truths that are calculated to heal the desperate wounds ye have received; that are suitable to inspire you with courage, sturdily to oppose yourselves to such dangerous errors; that have power to enable you to resist such formidable enemies. 30 If you throws down the temples, overturns the altars, so frequently bathed with the bitter tears of the unfortunate, blackened by the most cruel sacrifices, smoked with servile incense, 31 it is that you may erect a fane sacred to peace; a hall dedicated to reason; a durable monument to virtue, 32 in which ye may at all times find an asylum against your own phrenzy; a refuge from your own ungovernable passions; a sanctuary against those powerful dogmatists, by whom ye are oppressed. 33 If you attacks the haughty pretensions of deified tyrants, who crush ye with an iron sceptre, 34 it is that ye may enjoy the rights of your nature; it is to the end that ye may be substantively freemen, in mind as

well as in body; that ye may not be slaves, eternally chained to the oar of misery; 35 it is that ye may at length be governed by people who are citizens, who may cherish their own semblances, who may protect mortals like themselves, who may actually consult the interests of those from whom they hold their power. 36 If you battles with imposture, it is to re-establish truth in those rights which have been so long usurped by fiction. 37 If you undermines the base of that unsteady, fanatical morality, which has hitherto done nothing more than perplex your minds, without correcting your hearts; 38 it is to give to ethics an immovable basis, a solid foundation, secured upon your own nature; upon the reciprocity of those wants which are continually regenerating in sensible beings: 39 dare, then, to listen to His voice; you will find it much more intelligible than those ambiguous oracles, which are announced to you as the offspring of capricious theories; as imperious decrees that are unceasingly at variance with themselves. 40 Listen then to Nature, She never contradicts Her own eternal laws.

41 "O thou!" cries this Nature to man, "who, following the impulse I have given you, during your whole existence, incessantly tend towards happiness, do not strive to resist my sovereign law. 42 Labour to your own felicity; partake without fear of the banquet which is spread before you, with the most hearty welcome; you will find the means legibly written on your own heart. 43 Vainly dost thou, O superstitious being! Seek after thine happiness beyond the limits of the universe, in which my hand hath placed thee: 44 vainly shalt thou search it in those inexorable theories, which thine imagination, ever prone to wander, would establish upon my eternal throne: 45 vainly dost thou expect it in those fanciful regions, to which thine own

delirium hath given a locality and a shame: 46 vainly dost thou reckon upon capricious systems, with whose advantages thou art in such ecstasies; whilst they only fill thine abode with calamity-- thine heart with dread-- thy mind with illusions-- thy bosom with groans. 47 Know that when thou neglectest my counsels, the gods will refuse their aid.

48 Dare, then, to affranchise thyself from the trammels of superstition, my self-conceited, pragmatic rival, who mistakes my rights; 49 renounce those empty theories, which are usurpers of my privileges; return under the dominion of my laws, which, however severe, are mild in comparison with those of bigotry. 50 It is in my empire alone that true liberty reigns. Tyranny is unknown to its soil; equity unceasingly watches over the rights of all my subjects, maintains them in the possession of their just claims; 51 benevolence, grafted upon humanity, connects them by amicable bonds; truth enlightens them; never can imposture blind them with own obscuring mists. 52 Return, then, my child, to thy fostering mother's arms! Deserter, trace back thy wandering steps to Nature! She will console thee for thine evils; 53 She will drive from thine heart those appalling fears which overwhelm thee; those inquietudes that distract thee; those transports which agitate thee; those hatreds that separate thee from thy fellow human, whom thou shouldst love as thyself. 54 Return to Nature, to humanity, to thyself!

55 Strew flowers over the road of life: cease to contemplate the future; live to thine own happiness; exist for thy fellow creatures; retire into thyself, examine thine own heart, then consider the sensitive beings by whom thou art surrounded: 56 leave to their inventors those systems which can effect nothing towards thy felicity. 57 Enjoy

thyself, and cause others also to enjoy, those comforts which I have placed with a liberal hand, for all the children of the earth; who all equally emanate from my bosom: 58 assist them to support the sorrows to which necessity has submitted them in common with thyself. 59 Know, that I approve thy pleasures, when without injuring thyself, they are not fatal to thy brethren, whom I have rendered indispensably necessary to thine own individual happiness. 60 These pleasures are freely permitted thee, if thou indulgest them with moderation; with that discretion which I myself have fixed. 61 Be happy, then, O human! Nature invites thee to participate in it; but always remember, thou canst not be so alone; because I invite all mortals to happiness as well as thyself; thou will find it is only in securing their felicity that thou canst consolidate thine own. 62 Such is the decree of thy destiny: if thou shalt attempt to withdraw thyself from its operation, recollect that hatred will pursue thee; vengeance overtake thy steps; and remorse be ever ready at hand to punish the infractions of its irrevocable mandates.

63 "Follow then, O human! in whatever station thou findest thyself, the routine I have described for thee, to obtain that happiness to which thou hast an indispensable right to challenge pretension. 64 Let the sensations of humanity interest thee for the condition of other humans, who are thy fellow creatures; let thine heart have commiserations for their misfortunes: 65 let thy generous hand spontaneously stretch forth to lend succour to the unhappy mortal who is overwhelmed by your destiny; always bearing in thy recollection, that it may fall heavy upon thyself, as it now does upon your fellow. 66 Acknowledge, then, without guile, that every unfortunate has an inalienable right to thy kindness. 67 Above all, wipe from the eyes of oppressed

innocence the trickling crystals of agonised feeling; let the tears of virtue in distress, fall upon thy sympathising bosom; 68 let the genial glow of sincere friendship animate thine honest heart; let the fond attachment of a mate, cherished by thy warmest affection, make thee forget the sorrows of life: 69 be faithful to Her love, responsible to Her tenderness, that She may reward thee by a reciprocity of feeling; 70 that under the eyes of parents united in virtuous esteem, thy offspring may learn to set a proper value on practical virtue; 71 that after having occupied thy riper years, they may comfort thy declining age, gild with content thy setting sun, cheer the evening of thine existence, by a dutiful return of that care which thou shalt have bestowed on their imbecile infancy.

72 "Be just, because equity is the support of human society! Be good, because goodness connects all hearts in adamantine bonds! Be indulgent, because feeble thyself, thou livest with beings who partake of thy weakness! 73 Be gentle, because mildness attracts attention! Be thankful, because gratitude feeds benevolence, nourishes generosity! Be modest, because haughtiness is disgusting to beings at all times well with themselves. 74 Forgive injuries, because revenge perpetuates hatred! Do good to those who injureth thee, in order to show thyself more noble than you are; to make a friend of those who was once thine enemy! 75 Be reserved in thy demeanor, temperate in thine enjoyment, chaste in thy pleasures, because voluptuousness begets weariness, intemperance engenders disease; forward manners are revolting: 76 excess at all times relaxes the springs of thy machine, will ultimately destroy thy being, and render thee hateful to thyself, contemptible to others. 77 "Be a faithful citizen; because the community is necessary to thine own security; to the enjoyment of

thine own existence; to the furtherance of thine own happiness. 78 Be loyal, but be brave; submit to legitimate authority; because it is requisite to the maintenance of that society which is necessary to thyself. 79 Be obedient to the laws; because they are, or ought to be, the expression of the public will, to which thine own particular will ought ever to be subordinate. 80 Defend thy country with zeal; because it is that which renders thee happy, which contains thy property, as well as those beings dearest to thine heart: 81 do not permit this common parent of thyself, as well as of thy fellow citizens, to fall under the shackles of tyranny; because from thence it will be no more than thy common prison. 82 If thy country, deaf to the equity of thy claims, refuses thee happiness--if, submitted to an unjust power, it suffers thee to be oppressed, withdraw thyself from its bosom in silence, but never disturb its peace.

83 "In short, be a human; be a sensible, rational being; be a faithful husband; a tender wife; an equitable master; a zealous citizen; labour to serve thy country by thy prowess; by thy talents; by thine industry; above all, by thy virtues. 84 Participate with thine associates those gifts which Nature has bestowed upon thee; diffuse happiness, among thy fellow mortals; inspire thy fellow citizens with content; 85 spread joy over all those who approach thee, that the sphere of thine actions, enlivened by thy kindness, illumined by thy benevolence, may re-act upon thyself; be assured that the person who makes others happy cannot the self be miserable.

86 In thus conducting thyself, whatever may be the injustice of others, whatever may be the blindness of those beings with whom it is thy destiny to live, thou wilt never be totally bereft of the recompense which is thy due; 87 no power on earth be able to ravish from thee that never

failing source of the purest felicity, inward content; 88 at each moment thou wilt fall back with pleasure upon thyself; thou wilt neither feel the rankling of shame, the terror of internal alarm, nor find thy heart corroded by remorse. 89 Thou wilt esteem thyself; thou wilt be cherished by the virtuous, applauded and loved by all good people, whose suffrages are much more valuable than those of the bewildered multitude. 90 Nevertheless, if externals occupy thy contemplation, smiling countenances will greet thy presence; happy faces will express the interest they have in thy welfare; jocund beings will make thee participate in their placid feelings. 91 A life so spent, will each moment be marked by the serenity of thine own soul, by the affection of the beings who environ thee; will be made cheerful by the friendship of thy fellows; will enable thee to rise a contented, satisfied guest from the general feast; 92 conduct thee gently down the declivity of life, lead thee peaceably to the period of thy days; for die thou must: but already thou wilt survive thyself in thought; thou wilt always live in the remembrance of thy friends; 93 in the grateful recollection of those beings whose comforts have been augmented by thy friendly attentions; thy virtues will, beforehand have erected to thy fame an imperishable monument: 94 if heaven occupies itself with thee, it will feel satisfied with thy conduct, when it shall thus have contented the earth.

95 "Beware, then, how thou complainest of thy condition; be just, be kind, be virtuous, and thou canst never be wholly destitute of felicity. 96 Take heed how thou enviest the transient pleasure of seductive crime; the deceitful power of victorious tyranny; the specious tranquillity of interested imposture; the plausible manners of venal justice; the showy, ostentatious parade of hardened opulence. 97

Never be tempted to increase the number of sycophants to an ambitious despot; to swell the catalogue of slaves to an unjust tyrant; 98 never suffer thyself to be allured to infamy, to the practice of extortion, to the commission of outrage, by the fatal privilege of oppressing thy fellows; 99 always recollect it will be at the expense of the most bitter remorse thou wilt acquire this baneful advantage. 100 Never be the mercenary accomplice of the spoilers of thy country; they are obliged to blush secretly whenever they meet the public eye.

101 "For, do not deceive thyself, it is I who punish, with an unerring hand, all the crimes of the earth; the wicked may escape the laws of human, but they never escape mine. 102 It is I who have formed the hearts, as well an the bodies of mortals; it is I who have fixed the laws which govern them. 103 If thou deliverest thyself up to voluptuous enjoyment, the companions of thy debaucheries may applaud thee; but I shall punish thee with the most cruel infirmities; these will terminate a life of shame with deserved contempt. 104 If thou givest, thyself up to intemperate indulgences, human laws may not correct thee, but I shall castigate thee severely by abridging thy days. 105 If thou art vicious, thy fatal habits will recoil on thine own head. 106 Nobles, those terrestrial divinities, whose power places them above the laws of humankind, are nevertheless obliged to tremble under the silent operation of my decrees. 107 It is I who chastise them; it is I who fill their breasts with suspicion; it is I who inspire them with terror; it is I who make them writhe under inquietude; it is I who make them shudder with horror, at the very name of august truth; 108 it is I who, amidst the crowd of nobles who surround them, make them feel the inward workings of shame;

the keen anguish of guilt; the poisoned arrows of regret; the cruel stings of remorse; 109 it is I who, when they abuse my bounty, diffuse weariness over their benumbed souls; it is I who follow uncreated, eternal justice; 110 it is I who, without distinction of people, know how to make the balance even; to adjust the chastisement to the fault; to make the misery bear its due proportion to the depravity; to inflict punishment commensurate with the crime.

111 The laws of human are just, only when they are in conformity with mine; your judgements are rational, only when I have dictated them: 112 my laws alone are immutable, universal, irrefragable; formed to regulate the condition of the human race, in all ages, in all places, under all circumstances.

113 "If thou doubtest mine authority, if thou questionest the irresistible power I possess over mortals, contemplate the vengeance I wreak on all those who resist my decrees. 114 Dive into the recesses of the hearts of those various criminals, whose countenances, assuming a forced smile, cover souls torn with anguish. 115 Dost thou not behold ambition tormented day and night, with an ardour which nothing can extinguish? 116 Dost not thou see the mighty conquerer become the lord of devastated solitudes; 117 their victorious career, marked by a blasted cultivation, reign sorrowfully over smoking ruins; govern unhappy wretches who curse them in their hearts; while their soul, gnawed by remorse, sickens at the gloomy aspect of their own triumphs? 118 Dost thou believe that the tyrant, encircled with own flatterers, who stun the self with their praise, is unconscious of the hatred which their oppression excites; 119 of the contempt which their vices draw upon them; of the sneers which their inutility call forth; of the scorn which their debaucheries entail

upon their name? 120 Dost thou think that the haughty courtier does not inwardly blush at the galling insults they brooks; 121 despise, from the bottom of their soul, those meannesses by which they are compelled to purchase favours; feel at their heart's core the wretched dependence in which their cupidity places them. 122 "Contemplate the indolent child of wealth, behold them a prey to the lassitude of unmeasured enjoyment, corroded by the satiety which always follows your exhausted pleasures. 123 View the miser with an emaciated countenance, the consequence of own penurious disposition, 124 whose callous heart is inaccessible to the calls of misery, groaning over the accumulating load of useless treasure, which at the expense of the self, they have laboured to amass. 125 Behold the gay voluptuary, the smiling debaucheé, secretly lament the health they have so inconsiderately damaged so prodigally thrown away: 126 see disdain, joined to hatred, reign between those adulterous married couples, who have reciprocally violated the sacred vows they mutually pledged at the altar of Hymen; 127 whose appetencies have rendered them the scorn of the world; the jest of their acquaintance; polluted tributaries to the surgeon. 128 See the liar deprived of all confidence; the knave stript of all trust; the hypocrite fearfully avoiding the penetrating looks of own inquisitive neighbour; the impostor trembling at the very name of formidable truth. 129 Bring under your review the heart of the envious, uselessly dishonoured; that withers at the sight of own neighbour's prosperity. 130 Cast your eyes on the frozen soul of the ungrateful wretch, whom no kindness can warm, no benevolence thaw, no beneficence convert into a genial fluid. 131 Survey the iron feelings of that monster whom the sighs of the unfortunate cannot mollify. 132 Behold the revengeful being nourished with venemous gall, whose very thoughts are serpents; who in own rage consumes the self. 133 Envy, if thou canst, the waking

slumbers of the homicide; the startings of the iniquitous judge; the restlessness of the oppressor of innocence; the fearful visions of the extortioner; whose couches are infested with the torches of the furies.

134 Thou tremblest without doubt at the sight of that distraction which, amidst their splendid luxuries, agitates those farmers of the revenue, 135 who fatten upon public calamnity-- who devour the substance of the orphan-- who consume the means of the widow-- who grind the hard earnings of the poor: 136 thou shudderest at witnessing the remorse which rends the souls of those reverend criminals, whom the uninformed believe to be happy, 137 whilst the contempt which they have for themselves, the unerring shafts of secret upbraidings, are incessantly revenging an outraged nation. 138 Thou seest, that content is forever banished the heart; quiet for ever driven from the habitations of those miserable wretches on whose minds I have indelibly engraved the scorn, the infamy, the chastisement which they deserve. 139 But, no! thine eyes cannot sustain the tragic spectacle of my vengeance. 140 Humanity obliges thee to partake of their merited sufferings; thou art moved to pity for these unhappy people, to whom consecrated errors renders vice necessary; whose fatal habits make them familiar with crime. 141 Yes; thou shunnest them without hating them; thou wouldst succour them, if their contumacious perversity had left thee the means. 142 When thou comparest thine own condition, when thou examinest thine own soul, thou wilt have just cause to felicitate thyself, if thou shalt find that peace has taken up Her abode with thee; that contentment dwells at the bottom of thine own heart. 143 In short, thou seest accomplished upon them, as well as, upon thyself, the unalterable decrees of destiny, which imperiously demand, that crime shall punish itself, that virtue never shall be destitute Of remuneration."

144 Such is the sum of those truths which are contained in the Code-of-Nature; such are the

doctrines, which its disciples can announce. 145 They are unquestionably preferable to that supernatural superstition which never does anything but mischief to the human species. 146 Such is the worship that is taught by that sacred reason, which is the object of contempt with the theologian; which meets the insult of the fanatic; who only estimates that which human can neither conceive nor practise; 147 who make your morality consist in fictitious duties; your virtue in actions generally useless, frequently pernicious to the welfare of society; 148 who for want of being acquainted with Nature, which is before their eyes, believe themselves obliged to seek in ideal worlds imaginary motives, of which everything proves the inefficacy. 149 The motive which the morality of Nature employs, is the self-evident interest of each individual, of each community, of the whole human species, in all times, in every country, under all circumstances. 150 Its worship is the sacrifice of vice, the practise of real virtues; its object is the conservation of the human race, the happiness of the individual, the peace of humankind; 151 its recompences are affection, esteem, and glory; or in their default, contentment of mind, with merited self-esteem, of which no power will ever be able to deprive virtuous mortals; 152 its punishments, are hatred, contempt, and indignation; which society always reserves for those who outrage its interests; from which even the most powerful can never effectually shield themselves.

153 Those nations who shall be disposed to practise a morality so wise, who shall inculcate it in infancy, whose laws shall unceasingly confirm it, will neither have occasion for superstition, nor for chimeras. 154 Those who shall obstinately prefer figments to their dearest interests, will certainly march forward to ruin. 155 If they

maintain themselves for a season, it is because the power of Nature sometimes drives them back to reason, in despite of those prejudices which appear to lead them on to certain destruction. 156 Superstition, leagued with tyranny, for the waste of the human species, are themselves frequently obliged to implore the assistance of a reason which they condemn; of a nature which they disdain; which they debase; which they endeavour to crush under the ponderous bulk of artificial theories. 157 Superstition, in all times so fatal to mortals, when attacked by reason, assumes the sacred mantle of public utility; 158 rests its importance on false grounds, founds its rights upon the indissoluble alliance which it pretends subsists between morality and itself; 159 notwithstanding it never ceases for a single instant to wage against it the most cruel hostility. It is, unquestionably, by this artifice, that it has seduced so many sages.

160 In the honesty of their hearts, they believe it useful to politics; necessary to restrain the ungovernable fury of the passions; 161 thus hypocritical superstition, in order to mask to superficial observers, its own hideous character, like the ass with the lion's skin, always knows how to cover itself with the sacred armour of utility; to buckle on the invulnerable shield of virtue; 162 it has therefore, been believed imperative to respect it, notwithstanding it felt awkward under these incumbrances; 163 it consequently has become a duty to favour imposture, because it has artfully entrenched itself behind the altars of truth; 164 its ears, however, discover its worthlessness; its natural cowardice betrays itself; it is from this entrenchment we ought to drive it; it should be dragged forth to public view; stripped of its surreptitious panoply; exposed

in its native deformity; 165 in order that the human race may become acquainted with its dissimulation; that humankind may have a knowledge of its crimes; 166 that the universe may behold its sacrilegious hands, armed with homicidal poniards, stained with the blood of nations, whom it either intoxicates with its fury, or immolates without pity to the violence of its passions.

167 The MORALITY OF NATURE is the only creed which Her interpreter offers to own fellow citizens; to nations; to the human species; to future races, weaned from those prejudices which have so frequently disturbed the felicity of their ancestors. 168 The friend of humankind cannot be the friend of delusion, which at all times has been a real scourge to the earth. 169 The APOSTLE OF NATURE will not be the instrument of deceitful chimeras, by which this world is made only an abode of illusions; 170 the adorer of truth will not compromise with falsehood; you will make no covenant with error; conscious it must always be fatal to mortals. 171 You knows that the happiness of the human race imperiously exacts that the dark unsteady edifice of superstition should be razed to its foundations; in order to elevate on its ruins a temple suitable to peace-- a fane sacred to virtue. 172 You feels it is only by extirpating, even to the most slender fibres, the poisonous tree, that during so many ages has overshadowed the universe, 173 that the inhabitants of this world will be able to use their own optics-- to bear with steadiness that light which is competent to illumine their understanding-- to guide their wayward steps-- to give the necessary ardency to their souls. 174 If your efforts should be vain; if you cannot inspire with courage, beings too much accustomed to tremble; you will, at least, applaud yourself for having dared the attempt.

NATURE

175 Nevertheless, you will not judge your exertions fruitless, if you have only been enabled to make a single mortal happy: if your principles have calmed the conflicting transports of one honest soul; if your reasoning have cheered up some few virtuous hearts. 176 At least you will have the advantage of having banished from your own mind the importunate terror of superstition; 177 of having expelled from your own heart the gall which exasperates zeal; of having trodden under foot those chimeras with which the uninformed are tormented. 178 Thus, escaped from the peril of the storm, you will calmly contemplate from the summit of your rock, those tremendous hurricanes which superstition excites; 179 you will hold forth a succouring hand to those who shall be willing to accept it; you will encourage them with your voice; 180 you will second them with your best exertions, and in the warmth of your own compassionate heart, you will exclaim: O NATURE; sovereign of all beings! and ye, Her adorable daughters, VIRTUE, REASON, and TRUTH! remain forever our revered protectors: 181 it is to you that belong the praises of the human race; to you appertains the homage of the earth. 182 Show, us then, O NATURE! that which human ought to do, in order to obtain the happiness which thou makest human desire. 183 VIRTUE! Animate us with thy beneficent fire. REASON! Conduct our uncertain steps through the paths of life. TRUTH! Let thy torch illumine our intellect, dissipate the darkness of our road. 184 Unite, O assisting deities! your powers, in order to submit the hearts of humankind to your dominion. 185 Banish error from our mind; wickedness from our hearts; confusion from our footsteps; cause knowledge to extend its salubrious reign; goodness to occupy our souls; serenity to dwell in our bosoms.

186 Let imposture, confounded, never again dare to show its head. Let our eyes, so long, either dazzled or blindfolded, be at length fixed upon those objects we ought to seek. 187 Dispel for ever those mists of ignorance, those hideous phantoms, together with those seducing chimeras, which only serve to lead us astray. 188 Extricate us from that dark abyss into which we are plunged by superstition; overthrow the fatal empire of delusion; crumble the throne of falsehood; wrest from their polluted hands the power they have usurped. 189 Command people, without sharing your authority with mortals: break the chains that bind them down in slavery: tear away the bandeau by which they are hoodwinked; allay the fury that intoxicates them; 190 break in the hands of sanguinary, lawless tyrants, that iron sceptre with which they are crushed to exile; the imaginary regions, from whence fear has imported them, those theories by which they are afflicted.

191 Inspire the intelligent being with courage; infuse energy into your system, that, at length, you may feel your own dignity; that you may dare to love yourself; to esteem your own actions when they are worthy; 192 that a slave only to your eternal laws, you may no longer fear to enfranchise yourself from all other trammels; 193 that blest with freedom, you may have the wisdom to cherish your fellow creature; and become happy by learning to perfection your own condition; 194 instruct you in the great lesson, that the high road to felicity, is prudently to partake yourself, and also to cause others to enjoy, the rich banquet which thou, O Nature! hast so bountifully set before you. 195 Console thy children for those sorrows to which their destiny submits them, by those pleasures which wisdom allows them to partake; teach them to be contented with their condition; to banish envy from their mind; to

yield silently to necessity. 196 Conduct them without alarm to that period which all beings must find; let them learn that time changes all things, that consequently they are made neither to avoid its scythe nor to fear its arrival.

A BRIEF SKETCH OF THE LIFE AND WRITINGS OF M. DE. MIRABAUD

Paul Henri Thiery (Baron D'Holbach)

58 At a time when we are on the eve of an important change in our governmental affairs, which must evidently lead either to the recovery and re-establishment of our liberties, or to a military despotism, 2 those who are connected with the press ought to use every exertion to enlighten their fellow-citizens, and to assert their right of canvassing, in the most free and unrestrained manner, every subject connected with the happiness of human.

3 The priesthood have ever been convenient tools in the hands of tyrants, to keep the bulk of the people in a degraded servility. 4 By the superstitious and slavish doctrines which they infuse into their minds, they prevent them from thinking for themselves and asserting their own independence. 5 At a moment when national schools are erecting in every quarter of the country, not with a sincere desire of enlightening the rising generation, but with the insidious design of instilling into their minds the doctrines of "Church and King," 6 in order to bolster up a little longer the present rotten, tottering, and corrupt system: 7 at a moment, too, when thousands of fanatic preachers are traversing the country, with a view to subjugate the human mind to the baleful empire of visonary enthusiasm and sectarian bigotry to the utter extinction of every noble, humanly, liberal, and pilanthropic principle;-- 8 at such a moment as this, we thought that the "SYSTEM OF NATURE" could not fail to render essential service to the cause both of civil and religious liberty. 9 No work, ancient or modern, has surpassed it, in the eloquence and sublimity of its

language, or in the facility with which it treats the most abtruse and difficult subjects. 10 It is, without exception, the boldest effort the human mind has yet produced, in the investigation of morals and theology-- in the destruction of priestcraft and superstition-- 11 and in developing the sources of all those passions and prejudices which have proved so fatal to the tranquillity of the world.

12 The republic of letters has never produced an author whose pen was so well calculated to emancipate humankind from all those trammels 13 with which the nurse, the schoolmaster and the priest have successively locked up their noblest faculties, before they were capable of reasoning and judging for themselves. 14 The frightful apprehensions of the gloomy bigot, and all the appalling terrors of superstition, are here utterly annihilated, to the complete satisfaction of every unbiassed and impartial person. 15 These we considered as necessary observations to make, previous to any attempt at the biography of the author.

16 Biography may be reckoned among the most interesting of literary productions. Its intrinsic value is such, that, though capable of extraordinary embellishment from the hand of genius, yet no inferiority of execution can so degrade it, as to deprive it of utility. 17 Whatever relates even to human in general, considered only as an aggregate of active and intelligent beings, has a strong claim upon our notice; 18 but that which relates to our author, as distinguished from the rest of own species, moving in a more exalted sphere, 19 and towering above them by the resplendent excellencies of own mind, seems to me to be peculiarly calculated for our contemplation, and ought to form the highest pleasure of our lives. 20 There is a principle of curiosity implanted in us, which leads us, in an especial manner, to investigate our fellow creatures; 21 the eager

inquisitiveness with which the mechanic seeks to know the history of own fellow-workmen 22 and the ardour with which the philosopher, the poet, or the historian hunts for details that may familiarise the self with, a Descartes or a Newton, with a Milton, a Hume, or a Gibbon-- spring from the same source. 23 Their object, however, may perhaps vary; for, in the former, it may be for the sake of detraction, invidious cavil, or malice; in the latter, it is a sweet homage paid by the human heart to the memory of departed genius.

24 It has been repeatedly observed that the life of a scholar affords few materials for biography. This is only negatively true;-- 25 could every scholar have a Boswell, the remark would vanish; or were every scholar a Rousseau, a Gibbon, or a Cumberland it would be equally nugatory. 26 What can present higher objects of contemplation-- what can claim more forcibly our attention-- where can we seek for subjects of a more precious nature, than in the elucidation of the operations of mind, the acquisition of knowledge, the gradual expansion of genius; 27 its application, its felicities, its sorrows, its wreaths of fame, its cold, undeserved neglect? 28 Such scenes, painted by the artist, are a rich bequest to humankind: even when traced by the hand of friendship or the pencil of admiration, they possess a permanent interest in our hearts.

29 I cannot conceive a life more worthy of public notice, more important, more interesting to human nature, than the life of a literary person, were it executed according to the ideas I have formed of it: 30 did it exhibit a faithful delineation of the progress of intellect, from the cradle upwards; did it portray, in accurate colours, the production of what we call genius: by what accident it was first awakened; 31 what were its first tendencies; how directed to a particular object; by what means it was nourished and unfolded; the gradual progress of its operation in the production of a work; its hopes

and fears; its delights; its miseries; its inspirations; 32 and all the thousand fleeting joys that so often invest its path but for a moment, and then fade like the dews of the morning. 33 Let it contain too a transcript of the many nameless transports that float round the heart, that dance in the gay circle before the ardent gazing eye, when the first conception of some future effort strikes the mind; 34 how it pictures undefined delights of fame and popular applause; 35 how it anticipates the bright moments of invention, and dwells with prophetic ecstasy on the felicitous execution of particular parts, that already start into existence by the magic touch of a heated imagination. 36 Let it depict the tender feelings of solitude, the breathings of midnight silence, the scenes of mimic life, of imaged trial, that often occupy the musing mind; 37 let it be such a work, so drawn, so coloured, and who shall pronounce it inferior? 38 Who rather will not confess that it presents a picture of human nature, where every heart may find some corresponding harmony?

39 When, therefore, it is said, that the life of a scholar is barren, it is so only because it has never been properly delineated; 40 because those parts only have been selected which are common, and fail to distinguish you from the common human; 41 because we have never penetrated into your closet, or into your heart; because we have drawn you only as an outward figure, and left unnoticed that internal structure that would delight, astonish, and improve. 42 And then, when we compare the life of such a person with the more active one of a soldier, a statesman, or a lawyer, we pronounce it insipid, uninteresting. 43 True;-- the person of study has not fought for hire-- you have not slaughtered at the command of a master: you would disdain to do so. 44 Though unaccompanied with the glaring actions of public persons, which confound and dazzle by their publicity, but shrink from the estimation of moral truth, it would present a far nobler picture; yes, and a more instructive one:-- 45 the calm

disciple of reason meditates in silence; you walks your road with innoxious humility; you are poor, but your mind is your treasure; you cultivates your reason, and She lifts you to the pinnacle of truth; 46 you learns to tear away the veil of self-love, folly, pride, and prejudice, and bares the human heart to your inspection; you corrects and amends; you repairs the breaches made by passion; 47 the proud person passes you by, and looks upon you with scorn; but you feels your own worth, that ennobling consciousness which swells in every vein, and inspires you with true pride-- with humanly independence: 48 to such a person I could sooner bow in reverence, than to the haughtiest, most successful candidate for the world's ambition. But of such people, for the reason I have already mentioned, our information is scanty. 49 While of others, who have commanded a greater share of public notoriety, venal or mistaken admiration has given more than we wished to know. 50 Among these respected individuals of human nature, may be placed Mirabaud. 51 Had Mirabaud been an Englishman, who doubts but that we should have possessed at least ample details of the usual subjects of biographical notice; while all that has been collected among his own countrymen, is a scanty memoir in a common dictionary. 52 That we are doomed to remain ignorant of the life of such people, speaks a loud disgrace.-- I lament it.

53 JOHN BAPTISTE MIRABAUD, was born at Paris in the year 1674. He prosecuted his infantile studies under the direction of his parents, 54 and was afterwards entered a member of the Congregation of the Priests of the Oratory, where he passed several years, and produced some very bold writings, which were never intended for publication. 55 He was subsequently appointed tutor to the princesses of the House of Orleans, and then took the resolution of destroying the greater part of the manuscripts that he produced while a member of the Congregation; 56 but the treachery of some of his friends, to whom he had confided his manuscripts, rendered this precaution

useless, for some of his works were published during the time he remained the preceptor to his royal pupils; 57 among which number may be reckoned his "New Liberties of Thought," a work but little calculated for gaining him friends in the purlieus of the Court of Orleans. 58 The "Origin and Antiquity of the World," in three parts, was also published at this period, and from the publication of this work, may be dated the resolution of M. de Mirabaud to quit his office of preceptor, which he relinquished, having become more independent; 59 he now gave himself up entirely to his philosophical studies, and produced the "System of Nature," with which he was assisted by Diderot, D'Alembert, Baron D'Olbac, and others.

60 The profound metaphysical knowledge displayed throughout the System of Nature, and the doctrines which are therein advanced, warrants the conclusion, that it is at once the most decisive, boldest, and most extraordinary work, that the human understanding ever had the courage to produce. 61 The study of metaphysics is generally been considered the most terrific to the indolent mind; 62 but the clear and perspicuous reasoning of a Mirabaud, who has united the most profound argument, with the most fascinating eloquence, charm and instruct us at the same time. 63 But it was not, to be expected that such doctrines as are contained in the System of Nature, would be advanced without meeting with some opposition from the superficial and bigoted metaphysicians, who feel an interest in upholding a system of delusion and superstition. 64 No! Certainly not, their interest was threatened, and their craft in danger, and the consequence was, that the Atheists or Disciples of Nature has been abused with every scurrilous epithet, "full of sound and fury, signifying nothing."

65 Atheism is stigmatised with having "opened a wide door for

libertinism, destroying the social and moral compact; and striking a deadly blow at religion. 66 It is asserted that the atheist, who by own opinions has deprived the self of the hope and consolation of a future life, has no motive for the practise of virtue, or to contribute to the well being of society. 67 Deprived of a chimera which religion everywhere presents you, you wanders through the cheerless gloom of scepticism, regardless of the consequences of an abandoned life. 68 Without a God, you acknowledges no benefactor; without divine laws, you knows no rule for the conduct of life, and submits to no law but your passions. 69 An enemy to all social order, you spurns at human laws, and breaks through every barrier opposed to your wickedness." 70 Under such colours is an atheist painted: a short digression must be suffered to examine this picture, and to disprove the assertions so sweepingly made.

71 I admit that atheism strikes a deadly blow at religion; because under the cloak of religion, humankind have been oppressed in all ages; but that it encourages libertinism, or destroys the "social and moral compact," 72 I have yet to learn. In all organised governments, people are restrained from crime and compelled to submission by laws supposed to be made for the general benefit. 73 These laws are the effect of the first formation of society for mutual preservation. Here then is a sufficient motive for the one as well as the other, to contribute to the well-being of society. 74 The laws of Nature are the same in effect on the atheist and the religionist. If human be led captive by own passions, and gives the self to debauchery and voluptuousness, Nature will punish those with bodily infirmities and a debilitated mind. 75 If you be intemperate, She will shorten your days and bring you to the grave with the most poignant remorse. The fatal effects of your vicious propensities will fall upon your own head.

76 A disturber of social order will live in continual fear of the vengeance of society, and that very fear is a more dreadful punishment than the just vengeance which perhaps you escapes. 77 It renders life burdensome, and makes a person hateful to the self. 78 Can people have stronger motives for the practise of virtue? The atheist is in full possession of these motives, and the religionist is most completely swayed by them, whatever may be your pretensions to others derived from religion. 79 But we are assured you have other motives; more powerful incentives, in the promise of future rewards and punishments. 80 This, like all other chimerical doctrines, cannot be maintained if we look at the general practise of humankind. Let us trace the effects of this doctrine, 81 or rather let us examine the actions, conduct, and character of people professing it, and we shall see how little influence it has over them.

82 The bulk of society believes they shall answer in a future life for the deeds done in the present. Nay, I hardly think one in a hundred thousand will say they doubt it. 83 What then is its effect? With this dreadful sentence, "Thou shalt go into everlasting punishment," continually sounded in their ears, do we not daily see the greatest enormities committed? 84 Are not the most horrid crimes perpetrated in all parts of the world? The most vicious propensities and the most extravagant follies are almost indiscriminately gratified. 85 Is not vice frequently triumphant, and virtue compelled to seek its own reward in retirement?

86 The laws of society are broken by the most flagrant injustice, and the laws of Nature outraged by the most shocking depravity. 87 All this evil exists in nations believing themselves to be accountable beings after death. Where then are the beneficial effects arising, to humankind from the promulgation of this doctrine? 88 People who cannot be restrained from doing evil by

human laws, have no dread of any other. Their whole lives and conduct confirm this. 89 Others who live in submission to the laws of society, give themselves up to those vicious habits,-- without fear of divine laws-- which the law does not take cognisance of. 90 People, not wholly depraved, or not without the pale of society, generally respect the laws, and fear the bad opinion of others. 91 Hence we observe, when interest or passion leads them into secret vices, they invariably play the hypocrite; 92 and although they are aware of the denunciations of their God, whom they acknowledge is a witness to all their actions, while they preserve their fair fame they still persevere. 93 In fact, they live as if they disbelieved in own existence; and yet the greatest criminal, the most depraved wretch, would shudder at being told there is no God.

94 The atheist, as a person, is liable to commit the same crimes, and fall into the same vices as the believer; but because you are an atheist, is you a worse criminal than the other? 95 In one respect, I conceive you are not so bad. You only acts in defiance of human laws,-- you only offends people; the other infringes both divine and human;-- you defies both God and humanity. 96 Both are injurious to society and themselves, and both are actuated by the same motives.

97 Again we are told, that the well disposed part of humankind are rendered more virtuous, and the vicious left vicious by this doctrine. How are we to know that? 98 If the virtuous person acts uprightly, does good to own fellow creatures, restrains own passions, and returns good for evil, experience teaches you it is your interest so to do. 99 Those who are viciously disposed are only deterred from crime by penal laws. Societies cannot long exist, where evil has the ascendency. Without social laws, this would really be the case, notwithstanding the threats of an

avenging God. 100 If people were told they would not be answerable for the evil committed in this life to human laws, but that God would punish them after death, it is evident the human race would soon be exterminated.

101 On the other hand, tell them their crimes will never be punished by God, or, in other words, there is no other God than NATURE, but that the laws of humans will avenge the offences against society; 102 so long as those laws are administered with justice and impartiality, so long will such society continue to improve. Hence it is evident that the system which will maintain order in society by itself, must be the best and most rational. 103 A good government without religion would be more solid and lasting, and tend more to the preservation of humankind, than all the theocratical or ecclesiastical governments that ever the world was subject to. Thus much for the opponents of atheism.

104 It has been asserted with a perverse obstinacy, by the advocates for the existence of a deity, that the SYSTEM OF NATURE was never written by the author whose name it bears. 105 It is granted that it was not published during his life: but that circumstance forms no reason why such a conclusion should be drawn. 106 The persecutions which the atheists have endured, were a sufficient excuse for the work not appearing in any form during the life time of its venerable author. 107 The Athenians sought to try Diagoras the Melian, for atheism; but he fled from Athens, and a price was offered for his head. 108 Protagoras was banished from Athens, and his books burnt, because he ventured to assert, that he knew nothing of the gods. 109 Stephen Dolet was burnt at Paris for atheism. Giordano Bruno was burnt by the Inquisitors in Italy. Lucilio Vanini was burnt at Thoulouse, through the kind offices of an Attorney-General. 110 Bayle was under the necessity of fleeing to

Holland. Casimio Liszynski was executed at Grodno;-- and Akenhead at Edinborough. 111 And the body of the eloquent and erudite Hume, was obliged to be watched many nights by his friends, lest it should be taken up by the fanatics, who considered him one of the greatest monsters of iniquity, because he did not happen to believe as they believed. 112 With these pictures of Christian persecution before his eyes, is it surprising that M. de Mirabaud should adopt the resolution of suffering the SYSTEM OF NATURE to appear as a posthumous work? 113 That the same fate would have attended him, the most devout Christian will not undertake to deny. 114 However the sentiments of M. de Mirabaud may be condemned by the fanatics, all those who knew him bear the most brilliant testimony of his integrity, candour, and the soundness of his understanding; in a word, to his social virtues, and the innocence of his manners. 115 He died universally regretted, at Paris, the twenty-fourth of June, 1760, in the 1860 year of his age. 116 The following works, written by him at different periods, were never published:-- *The Life of Jesus Christ*. *Impartial Reflections on the Gospel*. The Morality of Nature. An Abridged History of the Priesthood; Ancient and Modern. The Opinions of the Ancients concerning the Jews. 117 A wretched mutilated edition of this last work was published at Amsterdam, in 1740, in two small volumes, under the title of Miscellaneous Dissertations.

The Fourth Book of Divine Panagogue called

METAPHYSICS

WHAT IS METAPHYSICS?

George Stuart Fullerton

1 The reader has probably already remarked that in the two of the preceding Books the adjectives metaphysical and philosophical have been used as if they were interchangeable, in certain connections, at least. 2 This is justified by common usage; and in the present chapter I shall be expected by no one, I think, to prove that metaphysics is a philosophical discipline. 3 My task will rather be to show how far the words "metaphysics" and "philosophy" have a different meaning. 4 In the Book of Theosophy, I have given a general view of the problems which present themselves to reflective thought, 5 and I have indicated that they are not problems which can conveniently be distributed among the several special sciences. 6 Is there an external world? What is it? What are space and time? What is the mind? How are mind and body related? How do we know that there are other minds than ours? 7 These have been presented as philosophical problems; 8 and when we turn back to the history of speculative thought we find that they are just the problems with which the people whom we agree to call philosophers have chiefly occupied themselves. 9 But when we turn to our treatises on metaphysics, we also find that these are the problems there discussed. 10 Such treatises differ much among themselves, and the problems are not presented in the same form or in the same order; 11 but one who can look beneath the surface will find that the authors are busied with much the same thing-- with some or all of the problems above mentioned.

12 How, then, does metaphysics differ from philosophy? 13 The difference becomes clear to us when we realise that the word philosophy has a broader and looser signification, and that metaphysics is, so to speak, the core, the citadel, of philosophy.

14 We have seen in the Theosophy that the world and the mind, as they seem to be presented in the experience of the plain person, do not stand forth with such clearness and distinctness that you are able to answer intelligently the questions we wish to ask you regarding their nature. 15 It is not merely that your information is limited; it is vague and indefinite as well. 16 And we have seen, too, that, however the special sciences may increase and systematise your information, they do not clear away such vagueness. 17 The person still uses such concepts as "inner" and "outer," "reality," "the mind," "space," and "time," with no very definite notion of what they mean.

18 Now, the attempt to clear away this vagueness by the systematic analysis of such concepts-- in other words, the attempt to make a thorough analysis of our experience-- is metaphysics. 19 The metaphysician strives to limit their task as well as they may, and to avoid unnecessary excursions into the fields occupied by the special sciences, even those which lie nearest to their own, such as psychology and ethics. 20 There is a sense in which you may be said to be working in the field of a special science, though you are using as the material for your investigations concepts which are employed in many sciences; 21 but it is clear that your discipline is not a special science in the same sense in which geometry and physics are special sciences.

22 Nevertheless, the special sciences stand, as we have already seen in the case of several of them, very near to your own. 23 If you broadens your view, and deliberately determines to take a survey of the field of human knowledge as illuminated by the analyses that you are made, you becomes something more than a metaphysician; you becomes a philosopher. 24 This does not in the least mean that you becomes a storehouse of miscellaneous information, and an authority on all the sciences. 25 Sometimes the philosophers have attempted to describe the world of matter and of mind as though they possessed some mysterious power 26 of knowing things that absolved them from the duty of traveling the

weary road of observation and experiment that has ended in the sciences as we have them. 27 When they have done this, they have mistaken the significance of their calling. 28 A philosopher has no more right than another person to create information out of nothing.

29 But it is possible, even for one who is not acquainted with the whole body of facts presented in a science, to take careful note of the assumptions upon which that science rests, 30 to analyse the concepts of which it makes use, to mark the methods which it employs, and to gain a fair idea of its scope and of its relation to other sciences. 31 Such a reflection upon our scientific knowledge is philosophical reflection, and it may result in a classification of the sciences, and in a general view of human knowledge as a whole. 32 Such a view may be illuminating in the extreme; it can only be harmful when its significance is misunderstood. 33 But, it may be argued, why may not the person of science do all this for the self? Why should you leave it to the philosopher, who is presumably less intimately acquainted with the sciences than you are?

34 To this I answer: The work should, of course, be done by the person who will do it best. All our subdivision of labour should be dictated by convenience. 35 But I add, that experience has shown that the workers in the special sciences have not as a rule been very successful when they have tried to philosophise.

36 Science is an imperious mistress; she demands one's utmost efforts; 37 and when a person turns to philosophical reflection merely "by the way," and in the scraps of time at your disposal after the day's work is done, your philosophical work is apt to be rather superficial. 38 Moreover, it does not follow that, because a person is a good mathematician or chemist or physicist, you are gifted with the power of reflective analysis. 39 Then, too, such people are apt to be imperfectly acquainted with what has been done in the past; 40 and those who are familiar with the history of philosophy often have occasion to remark that what is laid before them, in ignorance of

the fact that it is neither new nor original, 41 is a doctrine which has already made its appearance in many forms and has been discussed at prodigious length in the centuries gone by.

42 In certain sciences it seems possible to ignore the past, to a great extent, at least. What is worth keeping has been kept, and there is a solid foundation on which to build for the future. 43 But with reflective thought it is not so. There is no accepted body of doctrine which we have the right to regard as unassailable. 44 We should take it as a safe maxim that the reflections of people long dead may be profounder and more worthy of our study than those urged upon our attention by the people of our day.

45 And this leads me to make a remark upon the titles given to works on metaphysics. It seems somewhat misleading to label them: "Outlines of Metaphysics" or "Elements of Metaphysics." 46 Such titles suggest that we are dealing with a body of doctrine which has met with general acceptance, and may be compared with that found in handbooks on the special sciences. 47 But we should realise that, when we are concerned with the profounder investigations into the nature of our experience, we tread upon uncertain ground and many differences of opinion obtain. 48 We should, if possible, avoid a false semblance of authority.

EPISTEMOLOGY

George Stuart Fullerton

2 We hear a great deal at the present day of Epistemology, or the Theory of Knowledge. I have not classed it as a distinct philosophical science, for reasons which will appear below. 2 We have seen that it is possible to treat of logic in a simple way without growing very metaphysical; 3 but we have also seen that when we go deeply into questions touching the nature of evidence and what is meant by truth and falsity, we are carried back to philosophical reflection at once. 4 We may, for convenience, group together these deeper questions regarding the nature of knowledge and its scope,

and call the subject of our study "Epistemology."

5 But it should be remarked, in the first place, that, when we work in this field, we are exercising a reflective analysis of precisely the type employed in making the metaphysical analyses contained in the Panagogue. 6 We are treating our experience as it is not treated in common thought and in science. 7 And it should be remarked, in the second place, that the investigation of our knowledge inevitably runs together with an investigation into the nature of things known, of the mind and the world. 8 Suppose that I give the titles of the chapters in Part III of Mr. Hobhouse's able work on "The Theory of Knowledge." 9 They are as follows: Validity; the Validity of Knowledge; the Conception of External Reality; Substance; the Conception of Self; Reality as a System; Knowledge and Reality; the Grounds of Knowledge and Belief. 10 Are not these topics metaphysical? Let us ask ourselves how it would affect our views of the validity and of the limits of our knowledge, 11 if we were converted to the metaphysical doctrines of John Locke, or of Bishop Berkeley, or of David Hume, or of Thomas Reid, or of Immanuel Kant.

12 We may, then, regard epistemology as a part of logic-- the metaphysical part-- or as a part of metaphysics; it does not much matter which we call it, since we mean the same thing. 13 But its relation to metaphysics is such that it does not seem worthwhile to call it a separate discipline. 14 Before leaving this subject there is one more point upon which I should touch, if only to obviate a possible misunderstanding.

15 We find in Professor Cornelius's clear little book, "An Introduction to Philosophy" (Leipzig, 1903), that metaphysics is repudiated altogether, and epistemology is set in its place. 16 But this rejection of metaphysics does not necessarily imply the denial of the value of such an analysis of our experience as I have in this work called metaphysical.

17 Metaphysics is taken to mean, not an analysis of experience, but a groping behind the veil of phenomena for some reality not given in experience. 18 In other

words, what Professor Cornelius condemns is what many of the rest of us also condemn under another name.

19 What he calls metaphysics, we call bad metaphysics; and what he calls epistemology, we call metaphysics. 20 The dispute is really a dispute touching the proper name to apply to reflective analysis of a certain kind.

21 As it is the fashion in certain quarters to abuse metaphysics, I set the reader on your guard. Some kinds of metaphysics certainly ought to be repudiated under whatever name they may be presented to us.

THE VALUE OF THE STUDY OF PHILOSOPHY

George Stuart Fullerton

The Question Of Practical Utility

3 Why should people study philosophy? The question is a natural one, for human is a rational being, and when the worth of a thing is not at once evident to you, you usually calls for proof of its worth. 2 Our professional schools, with the exception of schools of theology, usually pay little attention to philosophical studies; 3 but such studies occupy a strong position in our colleges, and a vast number of persons not students in the technical sense think it worth while to occupy themselves with them more or less. 4 Wherever liberal studies are prosecuted they have their place, and it is an honoured place. Is this as it should be?

5 Before we ask whether any given study is of practical value, it is wise to determine what the word "practical" shall be taken to mean. 6 Shall we say that we may call practical only such learning as can be turned to direct account in earning money later? 7 If we restrict the meaning of the word in this way, we seem to strike a blow at liberal studies in general.

8 Thus, no one would think of maintaining that the study of mathematics is not of practical value-- sometimes and to some persons. 9 The physicist and the engineer need to know a good deal about mathematics. But how is it with the merchant, the lawyer, the clergyman, the physician? 10 How much of their algebra, geometry,

and trigonometry do these remember after they have become absorbed in the practice of their several callings, 11 and how often do they find it necessary to use anything beyond certain simple rules of arithmetic?

12 Sometimes we are tempted to condemn the study of the classics as unpractical, and to turn instead to the modern languages and to the physical sciences. 13 Now, it is, of course, a fair question to ask what should and what should not be regarded as forming part of a liberal education, and I shall make no effort to decide the question here. 14 But it should be borne well in mind that one cannot decide it by determining what studies are practical in the sense of the word under discussion.

15 If we keep strictly to this sense, the modern languages are to the majority of Americans of little more practical value than are the Latin and Greek. 16 We scarcely need them except when we travel abroad, and when we do that we find that the concierge and the waiter use English with surprising fluency. 17 As for the sciences, those who expect to earn a living through a knowledge of them, seek, as a rule, that knowledge in a technical or professional school, 18 and the rest of us can enjoy the fruit of their labours without sharing them. 19 It is a popular fallacy that because certain studies have a practical value to the world at large, they must necessarily have a practical value to everyone, and can be recommended to the individual on that account. 20 It is worth while to sit down quietly and ask yourself how many of the bits of information acquired during the course of a liberal education are directly used in the carrying on of a given business or in the practice of a given profession.

21 Nevertheless, we all believe that liberal education is a good thing for the individual and for the race. One must not too much restrict the meaning of the word "practical." 22 A civilised state composed of people who know nothing save what has a direct bearing upon their especial work in life is an absurdity; it cannot exist. 23 There must be a good deal of general enlightenment and there must be a considerable number of

individuals who have enjoyed a high measure of enlightenment.

24 This becomes clear if we consider the part played in the life of the state by the humblest tradesman. 25 If you are to be successful, you must be able to read, write, and keep your accounts, and make, let us say, shoes. 26 But when we have said this, we have summed you up as a workman, but not as a man, and you are also a person. 27 You may marry, and make a good or a bad spouse, and a good or a bad father or mother. 28 You stands in relations to your neighbourhood, to the school, and to the church; and you are not without your influence. 29 You may be temperate or intemperate, frugal or extravagant, law-abiding or the reverse. You have your share, and no small share, in the government of your city and of your state. 30 Your influence is indeed far-reaching, and that it may be an influence for good, you are in need of all the intellectual and moral enlightenment that we can give you. 31 It is of the utmost practical utility to the state that you should know a vast number of things which have no direct bearing upon the making and mending of shoes.

32 And if this is true in the case of the tradesman, it is scarcely necessary to point out that the physician, the lawyer, the clergyman, and the whole army of those whom we regard as the leaders of people 33 and the molders of public opinion have spheres of non-professional activity of great importance to the state. They cannot be mere specialists if they would. 34 They must influence society for good or ill; and if they are ignorant and unenlightened, their influence cannot be good.

35 When we consider the life of human in a broad way, we see how essential it is that many people should be brought to have a share in what has been gained by the long travail of the centuries past. 36 It will not do to ask at every step whether they can put to direct professional use every bit of information gained. 37 Literature and science, sweetness and light, beauty and truth, these are the heritage of the modern world; and unless these permeate its very being, society must undergo

degeneration. 38 It is this conviction that has led to the high appreciation accorded by intelligent people to courses of liberal study, 39 and among such courses those which we have recognised as philosophical must take their place.

WHY PHILOSOPHICAL STUDIES ARE USEFUL

40 But let us ask a little more specifically what is to be gained by pursuing distinctively philosophical studies. 41 Why should those who go to college, or intelligent persons who cannot go to college, care to interest themselves in logic and ethics, psychology and metaphysics? 42 Are not these studies rather dry, in the first place, and rather profitless, in the second?

43 As to the first point, I should stoutly maintain that if they are dry, it is somebody's fault. 44 The most sensational of novels would be dry if couched in the language which some philosophers have seen fit to use in expressing their thoughts. 45 You who defines "existence" as "the still and simple precipitate of the oscillation between beginning to be and ceasing to be" has done your best to alienate our affections from the subject of your predilection. 46 But it is not in the least necessary to talk in this way about matters philosophical. You who is not a slave to tradition can use plain and simple language. 47 To be sure, there are some subjects, especially in the field of metaphysics, into which the student cannot expect to see very deeply at the outset of own studies. 48 People do not expect to understand the more difficult problems of mathematics without making a good deal of preparation; 49 but, unhappily, they sometimes expect to have the profoundest problems of metaphysics made luminous to them in one or two popular lectures.

50 Philosophical studies are not dry, when people are properly taught, and are in a position to understand what is said. They deal with the most fascinating of problems. 51 It is only necessary to pierce through the husk of words which conceals the thoughts

of the philosopher, and we shall find the kernel palatable, indeed. Nor are such studies profitless, to take up our second point. Let us see what we may gain from them.

52 Let us begin with logic-- the traditional logic commonly taught to beginners. Is it worth while to study this? Surely it is. 53 No one who has not tried to introduce the average under-graduate to logic can realise how blindly one uses own reasoning powers, 54 how unconscious you are of the full meaning of the sentences you employs, 55 how easily you may be entrapped by fallacious reasoning where you are not set on your guard by some preposterous conclusion touching matters with which you are familiar.

56 And you are not merely unconscious of the lapses in your processes of reasoning, and of your imperfect comprehension of the significance of your statements; 57 you are unconscious also of the mass of inherited and acquired prejudices, often quite indefensible, which you unquestioningly employs as premises. 58 You fairly represents the larger world beyond the walls of the college. It is a world in which prejudices are assumed as premises, and loose reasoning pass current and are unchallenged until they beget some unpalatable conclusion. 59 It is a world in which people take little pains to think carefully and accurately unless they are dealing with something touching which it is practically inconvenient to make a mistake.

60 You who studies logic in the proper way is not filling your mind with useless facts; you are simply turning the light upon your own thinking mind, and realising more clearly what you have always done rather blindly and blunderingly. 61 You may completely forget the "Barbara, Celarent, Darii, Ferioque prioris," and you may be quite unable to give an account of the moods and figures of the syllogism; 62 but you cannot lose the critical habit if you once has acquired it, and you cannot but be on your guard against yourself as well as against others. 63 There is a keen pleasure in gaining such insight. It gives a feeling of freedom and power, 64 and rids one of that horrid sense that,

although this or that bit of reasoning is certainly bad, it is impossible to tell just what is the matter with it. 65 And as for its practical utility, if it is desirable to get rid of prejudice and confusion, and to possess a clear and reasonable mind, then anything that makes for this must be of value.

66 Of the desirability that all who can afford the luxury of a liberal education should do some serious reading in ethics, it seems hardly necessary to speak. But I cannot forbear dwelling upon it again. 67 What thoughtful person is not struck with the variety of ethical standards which obtain in the same community? 68 The clergyman who has a strong sense of responsibility for the welfare of own flock is sometimes accused of not sufficiently realising the importance of a frank expression of the whole truth about things; 69 the person of science, whose duty it seems to be to peer into the mysteries of the universe, and to tell what you sees or what you guesses, 70 is accused of an indifference to the effect which your utterances may have upon the less enlightened who hear you speak; 71 many criticise the lawyer for a devotion to the interests of own client which is at times in doubtful harmony with the interests of justice in the larger sense; 72 in the business world commercial integrity is exalted, and lapses from the ethical code which do not assail this cardinal virtue are not always regarded with equal seriousness.

73 It is as though people elected to worship at the shrine of a particular saint, and were inclined to overlook the claims of others. 74 For all this there is, of course, a reason; such things are never to be looked upon as mere accident. 75 But this does not mean that these more or less conflicting standards are all to be accepted as satisfactory and as ultimate. 76 It is inevitable that those who study ethics seriously, who really reflect upon ethical problems, should sometimes criticise the judgments of their fellow-people rather unfavorably. 77 Of such independent criticism many persons have a strong distrust. 78 I am reminded here of an eminent mathematician who maintained

that the study of ethics has a tendency to distort the student's judgments as to what is right and what is wrong. 79 You had observed that there is apt to be some divergence of opinion between those who think seriously upon morals and those who do not, and you gave the preference to the unthinking majority.

80 Now, there is undoubtedly danger that the independent thinker may be betrayed into eccentricities of opinion which are unjustifiable and are even dangerous. 81 But it seems a strange doctrine that it is, on the whole, safer not to think, but rather to drift on the stream of public opinion. 82 In other fields we are not inclined to believe that the ignorant person, who has given no especial attention to a subject, is the one likely to be right. Why should it be so in morals?

83 That the youth who goes to college to seek a liberal education has a need of ethical studies becomes very plain when we come to a realisation of the curious limitations of own ethical training as picked up from own previous experience of the world. 84 You have some very definite notions as to right and wrong. 85 You are as ready to maintain the desirability of benevolence, justice, and veracity, as was Bishop Butler, who wrote the famous "Analogy "; 86 although, to be sure, you are most inarticulate when called upon to explain what constitutes benevolence, justice, or veracity. 87 But the strangest thing is, that you seems to place some of the most important decisions of your whole life quite outside the realm of right and wrong.

88 You may admit that a person should not undertake to be a clergyman, unless one possesses certain qualifications of mind and character which evidently qualify one for that profession. 89 But you does not see why you have not the right to become a wearisome professor or an incompetent physician, if you chooses to enter upon such a career. 90 Is a person not free to take up what profession one pleases? You must take the risk, of course; but if you fails, you fails.

91 And when you are asked to consider from the point of view of ethics the question of marriage and

its responsibilities, you are at first inclined to consider the whole subject as rather a matter for jest. 92 Has a person not the right to marry or remain single exactly as one pleases? And are you not free to marry any one whom you can persuade to accept you? 93 Thus, a decision, which may affect your whole life as much as any other that you can be called upon to make, which may practically make it or mar it, 94 is treated as though it were not a matter of grave concern, but a private affair, entailing no serious consequences to any one and calling for no reflection.

95 I wish it could be said that the world outside of the college regarded these matters in another light. But the student faithfully represents the opinions current in the community from which one comes. 96 And you represents, unhappily, the teachings of the stage and of the world of current fiction. 97 The influence of these is too often on the side of inconsiderate passion, which stirs our sympathy and which lends itself to dramatic effect. 98 With the writers of romance the ethical philosophers have an ancient quarrel.

99 It may be said: But the world gets along very well as it is, and without brooding too much upon ethical problems. 100 To this we may answer: Does the world get along so very well, after all? Are there no evils that foresight and some firmness of character might have obviated? 101 And when we concern ourselves with the educated classes, at least, the weight of whose influence is enormous, is it too much to maintain that they should do some reading and thinking in the field of ethics? 102 should strive to attain to clear vision and correct judgment on the whole subject of human's duties?

103 Just at the present time, when psychological studies have so great a vogue, one scarcely feels compelled to make any sort of an apology for them. 104 It is assumed on all hands that it is desirable to study psychology, and courses of lectures are multiplied in all quarters. 105 Probably some of this interest has its root in the fallacy. The science of psychology has revolutionised educational

theory. 106 When those of us who have arrived at middle life look back and survey the tedious and toilsome path along which we were unwillingly driven in our schoolboy days, 107 and then see how smooth and pleasant it has been made since, we are impelled to honour all who have contributed to this result. 108 Moreover, it seems very clear that teachers of all grades should have some acquaintance with the nature of the minds that they are labouring to develop, 109 and that they should not be left to pick up their information for themselves-- a task sufficiently difficult to an unobservant person. 110 These considerations furnish a sufficient ground for insisting that studies in behavioural science should form some part of the education of a teacher. But why should the rest of us care for such studies?

111 To this one may answer, in the first place, that nearly all of us have, or ought to have, some responsibility for the education of children; 112 and, in the second, that we deal with the minds of others every day in every walk in life, and it can certainly do no harm to have our attention called to the way in which minds function. 113 To be sure, some people are by nature tactful, and instinctively conscious of how things strike the minds of those about them. 114 But even such persons may gain helpful suggestions, and, at least, have the habit of attention to the mental processes of others confirmed in them. 115 How often we are impressed at church, at the public lecture, and in private conversations, with the fact that the speaker lives in blissful unconsciousness of what can be understood by or can possibly interest one's hearers! 116 For the confirmed bore, there is, perhaps, no cure; but it seems as though something might be done for those who are afflicted to a minor degree.

117 And this brings me to another consideration, which is that a proper study of behavioural-science ought to be of service in revealing to a person your own nature. 118 It should show you what you are, and this is surely a first step toward becoming something better. 119 It is

wonderful how blind people may be with regard to what passes in their own minds and with regard to their own peculiarities. 120 When they learn to reflect, they come to a clearer consciousness of themselves-- it is as though a lamp were lighted within them. 121 One may, it is true, study psychology without attaining to any of the good results suggested above; 122 but, for that matter, there is no study which may not be pursued in a profitless way, if the teacher be sufficiently unskilled and the pupil sufficiently thoughtless.

METAPHYSICS AND PHILOSOPHY OF RELIGION

123 Perhaps it will be said: For such philosophical studies as the above a good defense may perhaps be made, but can one defend in the same way the plunge into the obscurities of metaphysics? 124 In this field no two people seem to be wholly agreed, and if they were, what would it signify? 125 Whether we call ourselves monists or dualists, idealists or realists, Lockians or Kantians, must we not live and deal with the things about us in much the same way?

126 Those who have dipped into metaphysical studies deeply enough to see what the problems discussed really are; 127 who have been able to reach the ideas concealed, too often, under a rather forbidding terminology; 128 who are not of the dogmatic turn of mind which insists upon unquestioned authority and is repelled by the uncertainties which must confront those who give themselves to reflective thought,-- 129 these will hardly need to be persuaded that it is desirable to give some attention to the question: What sort of a world, after all, is this world in which we live? What is its meaning?

130 To many people the impulse to peer into these things is over-powering, and the pleasure of feeling their insight deepen is extremely keen. 131 What deters us in most instances is not the conviction that such investigations are not, or should not be, interesting, but rather the difficulty of the approach. 132 It is not easy to follow the path which leads from the world of common

thought into the world of philosophical reflection. One becomes bewildered and discouraged at the outset. 133 Sometimes, after listening to the directions of guides who disagree among themselves, we are tempted to believe that there can be no certain path to the goal which we have before us. 134 But, whatever the difficulties and uncertainties of our task, a little reflection must show that it is not one which has no significance for human life.

135 People can, it is true, eat and sleep and go through the routine of the day, without giving thought to science or religion or philosophy, but few will defend such an existence. 136 As a matter of fact, those who have attained to some measure of intellectual and moral development do assume, consciously or unconsciously, some rather definite attitude toward life, 137 and this is not independent of their conviction as to what the world is and means.

138 Metaphysical speculations run out into the philosophy of religion; and, on the other hand, religious emotions and ideals have again and again prompted people to metaphysical construction. 139 A glance at history shows that it is natural to human to embrace some attitude toward the system of things, and to try to justify this by reasoning. 140 Vigorous and independent minds have given birth to theories, and these have been adopted by others. The influence of such theories upon the evolution of humanity has been enormous.

141 Ideas have ruled and still rule the world, some of them very abstract ideas. 142 It does not follow that one is uninfluenced by them, when one has no knowledge of their source or of their original setting. 143 They become part of the intellectual heritage of us all, and we sometimes suppose that we are responsible for them ourselves. 144 Has not the fact that an idealistic or a materialistic type of thought has been current at a particular time influenced the outlook on life of many who have themselves devoted little attention to philosophy? 145 It would be interesting to know how many, to whom Spencer is but a name, have felt the influence of the

agnosticism of which he was the apostle.

146 I say this without meaning to criticise here any of the types of doctrine referred to. 147 My thesis is only that philosophy and life go hand in hand, and that the prying into the deeper mysteries of the universe cannot be regarded as a matter of no practical moment. 148 Its importance ought to be admitted even by the person who has little hope that you will yourself be able to attain to a doctrine wholly satisfactory and wholly unshakable.

149 For, if the study of the problems of metaphysics does nothing else for a given individual, it, at least, enables you to comprehend and criticise intelligently the doctrines which are presented for your acceptance by others. 150 It is a painful thing to feel quite helpless in the face of plausible reasoning which may threaten to rob us of our most cherished hopes, 151 or may tend to persuade us of the vanity of what we have been accustomed to regard as of highest worth. 152 If we are quite unskilled in the examination of such doctrines, we may be captured by the loosest of arguments-- witness the influence of Spencer's argument for the "Unknowable," in the "First Principles"; 153 and if we are ignorant of the history of speculative thought, we may be carried away by old and exploded notions which pose as modern and impressive only because they have been given a modern dress.

154 We can, of course, refuse to listen to those who would talk with us. But this savours of bigotry, and the world will certainly not grow wiser, if people generally cultivate a blind adherence to the opinions in which they happen to be brought up. 155 A cautious conservatism is one thing, and blind obstinacy is another. To the educated person a better way of avoiding error is open-- 156 and it is probable that others will have to depend on opinions taken at second hand.

157 Finally, it will not do to overlook the broadening influence of such studies as we are discussing. 158 How dogmatically people are in the habit of expressing themselves upon those obscure and difficult problems

which deal with matters that lie on the confines of human knowledge! 159 Such an assumption of knowledge cannot but make us uncomprehending and unsympathetic.

160 There are many subjects upon which, if we hold an opinion at all, we should hold it tentatively, waiting for more light, and retaining a willingness to be enlightened. 161 Many a bitter and fruitless quarrel might be avoided, if more persons found it possible to maintain this philosophical attitude of mind. 162 Philosophy is, after all, reflection, and the reflective person must realise that one is probably as liable to error as are other people. 163 You are not infallible, nor has the limit of human knowledge been attained in your day and generation. 164 You who realise this will not assume that your neighbour is always wrong, and you will come to have that wide, conscientious tolerance, which is not indifference, but which is at the farthest remove from the zeal of mere bigotry.

WHY WE SHOULD STUDY THE HISTORY OF RELIGION

George Stuart Fullerton

THE PROMINENCE GIVEN TO THE SUBJECT

4 When one reflects upon the number of lecture courses given every year at our universities and colleges on the history of philosophy, 2 one is struck by the fact that philosophy is not treated as are most other subjects with which the student is brought into contact.

3 If we study mathematics, or chemistry, or physics, or physiology, or biology, the effort is made to lay before us in a convenient form the latest results which have been attained in those sciences. 4 Of their history very little is said; and, lectures on the history of the inductive sciences are apt to be regarded as philosophical in their character and aims rather than as merely scientific.

5 The interest in the history of philosophy is certainly not a diminishing one. Text-books covering the whole field or a part of it are multiplied; 6 extensive

studies are made and published covering the work of individual philosophers; innumerable historical discussions make their appearance in the pages of current philosophical journals. 7 No student is regarded as fairly acquainted with philosophy who knows nothing of Plato and Aristotle, Descartes and Spinoza, Berkeley and Hume, Kant and Hegel, and the rest. 8 We should look upon those as having a very restricted outlook if they had read only the works of the thinkers of our own day; 9 indeed, we should not expect those to have a proper comprehension even of these, for their chapters must remain blind and meaningless to one who has no knowledge of what preceded them and has given birth to the doctrines there set forth.

10 It is a fair question to ask: Why is philosophy so bound up with the study of the past? 11 Why may we not content ourselves with what has up to the present been attained, and omit a survey of the road along which our predecessors have travelled?

THE ESPECIAL IMPORTANCE OF HISTORICAL STUDIES TO REFLECTIVE THOUGHT

12 In some of the preceding chapters dealing with the various philosophical sciences, it has been indicated that, in the sciences we do not regard as philosophical, 13 people may work on the basis of certain commonly accepted assumptions and employ methods which are generally regarded as trustworthy within the given field. 14 The value both of the fundamental assumptions and of the methods of investigation appear to be guaranteed by the results attained. 15 There are not merely observation and hypothesis; there is also verification, and where this is lacking, people either abandon their position or reserve their judgment.

16 Thus, a certain body of interrelated facts is built up, the significance of which, in many fields at least, is apparent even to the layman. 17 Nor is it wholly beyond you to judge whether the results of scientific investigations can be verified. 18 An eclipse, calculated by methods which you

are quite unable to follow, may occur at the appointed hour and confirm your respect for the astronomer. 19 The efficacy of a serum in the cure of diseases may convince you that work done in the labouratory is not labour lost.

20 It seems evident that the several sciences do really rise on stepping stones of their dead selves, and that those selves of the past are really dead and superseded. 21 Who would now think of going back for own science to Plato's "Timaeus," or would accept the description of the physical world contained in the works of Aristotle? 22 What chemist or physicist need busy the self with the doctrine of atoms and their clashings presented in the magnificent poem of Lucretius? 23 Who can forbear a smile-- a sympathetic one-- when you turns over the pages of Augustine's "City of God," and sees what sort of a world this remarkable man believed himself to inhabit?

24 It is the historic and human interest that carries us back to these things. We say: What ingenuity! what a happy guess! 25 how well that was reasoned in the light of what was actually known about the world in those days! 26 But we never forget that what compels our admiration does so because it makes us realise that we stand in the presence of a great mind, and not because it is a foundation-stone in the great edifice which science has erected.

27 But it is not so in philosophy. It is not possible to regard the philosophical reflections of Plato and of Aristotle as superseded in the same sense in which we may so regard their science. 28 The reason for this lies in the difference between scientific thought and reflective thought. 29 It was there pointed out that the sort of thinking demanded in the special sciences is not so very different from that with which we are all familiar in common life. 30 Science is more accurate and systematic, it has a broader outlook, and it is free from the imperfections which vitiate the uncritical and fragmentary knowledge which experience of the world yields the unscientific. 31 But, after all, the world is much the same sort of a world to the person of science and to own

uncritical neighbour. 32 The latter can, as we have seen, understand what, in general, the former is doing, and can appropriate many of own results.

33 On the other hand, it often happens that the person who has not, with pains and labour, learned to reflect, cannot even see that the philosopher has a genuine problem before the self. 34 Thus, the plain person accepts the fact that you have a mind and that it knows the world. 35 That both mental phenomena and physical phenomena should be carefully observed and classified you may be ready to admit. 36 But that the very conceptions of mind and of what it means to know a world are vague and indefinite in the extreme, and stand in need of careful analysis, you does not realise.

37 In other words, you sees that our knowledge needs to be extended and rendered more accurate and reliable, 38 but you does not see that, if we are to think clearly and consciously, all our knowledge needs to be done over in a different way. 39 In common life it is quite possible to use in the attainment of practical ends knowledge which has not been analysed and of the full meaning of which we are ignorant. 40 I hope it has become evident in the course of this volume that something closely analogous is true in the field of science. 41 The person of science may measure space and time, and may study the phenomena of the human mind, 42 without even attempting to answer all the questions which may be raised as to what is meant, in the last analysis, by such concepts as space, time, and the mind.

43 That such concepts should be analysed has, I hope, been made clear, if only that erroneous and misleading notions as to these things should be avoided. 44 But when a person with a genius for metaphysical analysis addresses the self to this task, you cannot simply hand the results attained by your reflections over to your less reflective fellow-person. 45 Your words are not understood; you seems to be dealing with shadows, with unrealities; 46 you have passed from the real world of common thought into another world which appears to have little

relation to the former. 47 Nor can verification, indubitable proof, be demanded and furnished as it can in many parts of the field cultivated by the special sciences. 48 We may judge science fairly well without ourselves being scientists, but it is not possible to judge philosophy without being to some extent a philosopher.

49 In other words, the conclusions of reflective thought must be judged by following the process and discovering its cogency or the reverse. 50 Thus, when the philosopher lays before us an argument to prove that we must regard the only ultimate reality in the world as unknowable, and must abandon our theistic convictions, 51 how shall we make a decision as to whether the philosopher is right or is wrong? 52 May we expect that the day will come when the philosopher will be justified or condemned as is the astronomer on the day predicted for an eclipse? 53 Neither the philosophy of Locke, nor that of Descartes, nor that of Kant, can be vindicated as can a prediction touching an eclipse of the sun. 54 To judge these people, we must learn to think with them, to survey the road by which they travel; and this we cannot do until we have learned the art.

55 Whether we like to admit it or not, we must admit, if we are fair-minded and intelligent, that philosophy cannot speak with the same authority as science, where science has been able to verify its results. 56 There are, of course, scientific hypotheses and speculations which should be regarded as being quite as uncertain as anything brought forward by the philosophers. 57 But, admitting this, the fact remains that there is a difference between the two fields as a whole, and that the philosopher should learn not to speak with an assumption of authority. 58 No final philosophy has been attained, so palpably firm in its foundation, and so admittedly trustworthy in its construction, 59 that we are justified in saying: Now we need never go back to the past unless to gratify the historic interest. 60 It is a weakness of young people, and of older people of partisan temper, to feel very sure of matters which,

in the nature of things, must remain uncertain.

61 Since these things are so, and since people possess the power of reflection in very varying degree, 62 it is not surprising that we find it worth while to turn back and study the thoughts of those who have had a genius for reflection, even though they lived at a time when modern science was awaiting its birth. 63 Some things cannot be known until other things are known; 64 often there must be a vast collection of individual facts before the generalisations of science can come into being. 65 But many of the problems with which reflective thought is still struggling have not been furthered 66 in the least by information which has been collected during the centuries which have elapsed since they were attacked by the early Greek philosophers.

67 Thus, we are still discussing the distinction between "appearance" and "reality," and many and varied are the opinions at which philosophers arrive. 68 But Thales, who heads the list of the Greek philosophers, had quite enough material, given in his own experience, 69 to enable him to solve this problem as well as any modern philosopher, had he been able to use the material. 70 You who is familiar with the history of philosophy will recognise that, although one may smile at Augustine's accounts of the races of people, and of the spontaneous generation of small animals, 71 no one has a right to despise own profound reflections upon the nature of time and the problems which arise out of its character as past, present, and future.

72 The fact is that metaphysics does not lag behind because of our lack of material to work with. The difficulties we have to face are nothing else than the difficulties of reflective thought. 73 Why can we not tell clearly what we mean when we use the word "self," or speak of "knowledge," or insist that we know an "external world"? 74 Are we not concerned with the most familiar of experiences? To be sure we are-- with experiences familiarly, but vaguely and unanalytically, known and, hence, only half known. 75 All these experiences the great people of the past had as well as we; and if they

had greater powers of reflection, perhaps they saw more deeply into them than we do. At any rate, we cannot afford to assume that they did not.

76 One thing, however, I must not omit to mention. Although one person cannot turn over bodily the results of own reflection to another, 77 it by no means follows that one cannot give the other a helping hand, or warn others of dangers by the self stumbling into pitfalls, as the case may be. 78 We have an indefinite advantage over the solitary thinkers who opened up the paths of reflection, for we have the benefit of their teaching.

THE VALUE OF DIFFERENT POINTS OF VIEW

79 The person who has not read is like the person who has not traveled-- you are not an intelligent critic, for you have nothing with which to compare what falls within the little circle of your experiences. 80 That the prevailing architecture of a town is ugly can scarcely impress one who is acquainted with no other town. 81 If we live in a community in which people's manners are not good, and their standard of living not the highest, our attention does not dwell much upon the fact, 82 unless some contrasted experience wakes within us a clear consciousness of the difference. 83 That to which we are accustomed we accept uncritically and unreflectively. 84 It is difficult for us to see it somewhat as one might see it to whom it came as a new experience.

85 Of course, there may be in the one town buildings of more and of less architectural beauty; 86 and there may be in the one community differences of opinion that furnish intellectual stimulus and keep awake the critical spirit. 87 Still, there is such a thing as a prevalent type of architecture, and there is such a thing as the spirit of the times. 88 You who is carried along by the spirit of the age may easily conclude that what is, is right, because you hears few raise their voices in protest.

89 To estimate justly the type of thought in which you have been brought up, you must have something with which to compare

it. 90 You must stand at a distance, and try to judge it as you would judge a type of doctrine presented to you for the first time. 91 And in the accomplishment of this task you can find no greater aid than the study of the history of philosophy.

92 It is at first something of a shock to a person to discover that assumptions which you have been accustomed to make without question have been frankly repudiated by people quite as clever as you, and, perhaps, more critical. 93 It opens the eyes to see that your standards of worth have been weighed by others and have been found wanting. 94 It may well incline you to reexamine reasoning in which you have detected no flaw, when you finds that acute minds have tried them before, and have declared them faulty.

95 Nor can it be without its influence upon your judgment of the significance of a doctrine, 96 when it becomes plain to you that this significance can scarcely be fully comprehended until the history of the doctrine is known. 97 For example, you thinks of the mind as somehow in the body, as interacting with it, as a substance, and as immaterial. 98 In the course of your reading it begins to dawn upon your consciousness that you have not thought all this out for yourself; 99 you have taken these notions from others, who in turn have had them from their predecessors. 100 You begins to realise that you are not resting upon evidence independently found in your own experience, but has upon your hands a sheaf of opinions which are the echoes of old philosophies, 101 and whose rise and development can be traced over the stretch of the centuries. 102 Can you help asking yourself, when you sees this, whether the opinions in question express the truth and the whole truth? Are you not forced to take the critical attitude toward them?

103 And when you views the succession of systems which pass in review before you, noting how a truth may be dimly seen by one writer, denied by another, taken up again and made clearer by a third, and so on, 104 how can you avoid the reflection that, as there was some error mixed with the truth presented in earlier systems, so

there probably is some error in whatever may happen to be the form of doctrine generally received in your own time? 105 The evolution of humanity is not yet at an end; people still struggle to see clearly, and fall short of the ideal; 106 it must be a good thing to be freed from the dogmatic assumption of finality natural to the person of limited outlook. 107 In studying the history of philosophy sympathetically we are not merely calling to our aid critics who possess the advantage of seeing things from a different point of view, 108 but we are reminding ourselves that we, too, are human and fallible.

PHILOSOPHY AS POETRY, AND PHILOSOPHY AS SCIENCE

109 The recognition of the truth that the problems of reflection do not admit of easy solution and that verification can scarcely be expected as it can in the fields of the special sciences, 110 need not, even when it is brought home to us, as it is apt to be, by the study of the history of philosophy, 111 lead us to believe that philosophies are like the fashions, a something gotten up to suit the taste of the day, and to be dismissed without regret as soon as that taste changes.

112 Philosophy is sometimes compared with poetry. It is argued that each age must have its own poetry, even though it be inferior to that which it has inherited from the past. 113 Just so, it is said, each age must have its own philosophy, and the philosophy of an earlier age will not satisfy its demands. 114 The implication is that in dealing with philosophy we are not concerned with what is true or untrue in itself considered, but with what is satisfying to us or the reverse.

115 Now, it would sound absurd to say that each age must have its own geometry or its own physics. 116 The fact that it has long been known that the sum of the interior angles of a plane triangle is equal to two right angles, does not warrant me in repudiating that truth; 117 nor am I justified in doing so, and in believing the opposite, merely because I find the statement uninteresting or

distasteful. 118 When we are dealing with such matters as these, we recognise that truth is truth, and that, if we mistake it or refuse to recognise it, so much the worse for us.

119 Is it otherwise in philosophy? Is it a perfectly proper thing that, in one age, people should be idealists, and in another, materialists; in one, theists, and in another, agnostics? 120 Is the distinction between true and false nothing else than the distinction between what is in harmony with the spirit of the times and what is not?

121 That it is natural that there should be such fluctuations of opinion, we may freely admit. 122 Many things influence a person to embrace a given type of doctrine, and, as we have seen, verification is a difficult problem. 123 But have we here, any more than in other fields, the right to assume that a doctrine was true at a given time merely because it seemed to people true at that time, or because they found it pleasing? 124 The history of science reveals that many things have long been believed to be true, and, indeed, to be bound up with what were regarded as the highest interests of human, and that these same things have later been discovered to be false-- 125 not false merely for a later age, but false for all time; as false when they were believed in as when they were exploded and known to be exploded. 126 No person of sense believes that the Ptolemaic system was true for a while, and that then the Copernican became true. 127 We say that the former only seemed true, and that the enthusiasm of its adherents was a mistaken enthusiasm.

128 It is well to remember that philosophies are brought forward because it is believed or hoped that they are true. 129 A fairy tale may be recited and may be approved, although no one dreams of attaching faith to the events narrated in it. 130 But a philosophy attempts to give us some account of the nature of the world in which we live. 131 If the philosopher frankly abandons the attempt to tell us what is true, and with a Celtic generosity addresses the self to the task of saying what will be agreeable to us, the philosopher

loses own right to the title. 132 It is not enough that you stirs our emotions, and works up your unrealities into something resembling a poem. 133 It is not primarily your task to please, as it is not the task of the serious worker in science to please those whom you are called upon to instruct. 134 Truth is truth, whether it be scientific truth or philosophical truth. 135 And error, no matter how agreeable or how nicely adjusted to the temper of the times, is always error. 136 If it is error in a field in which the detection and exposure of error is difficult, it is the more dangerous, and the more should we be on our guard against it.

137 We may, then, accept the lesson of the history of philosophy, to wit, that we have no right to regard any given doctrine as final in such a sense that it need no longer be held tentatively and as subject to possible revision; 138 but we need not, on that account, deny that philosophy is, what it has in the past been believed to be, an earnest search for truth. 139 A philosophy that did not even profess to be this would not be listened to at all. It would be regarded as too trivial to merit serious attention. 140 If we take the word "science" in the broad sense to indicate a knowledge of the truth more exact and satisfactory than that which obtains in common life, 141 we may say that every philosophy worthy of the name is, at least, an attempt at scientific knowledge. 142 Of course, this sense of the word "science" should not be confused with that in which it has been used elsewhere in this volume.

HOW TO READ THE HISTORY OF PHILOSOPHY

143 You who takes up the history of philosophy for the first time is apt to be impressed with the fact that you are reading something that might not inaptly be called the history of human error. 144 It begins with crude and, to the superficial spectator, seemingly childish attempts in the field of physical science. 145 There are clever guesses at the nature of the physical world, but the boldest of speculations are entered upon with

no apparent recognition of the difficulty of the task undertaken, and with no realisation of the need for caution. 146 Somewhat later a different class of problems makes its appearance-- the problems which have to do with the mind and with the nature of knowledge, 147 reflective problems which scarcely seem to have come fairly within the horizon of the earliest thinkers.

148 These problems even the beginner may be willing to recognise as philosophical; but you may conscientiously harbour a doubt as to the desirability of spending time upon the solutions which are offered. 149 System rises after system, and confronts you with what appear to be new questions and new answers. 150 It seems as though each philosopher were constructing a world for the self independently, and commanding you to accept it, without first convincing you of your right to assume this tone of authority and to set up for an oracle. 151 In all this conflict of opinions where shall we seek for truth? Why should we accept one person as a teacher rather than another? 152 Is not the lesson to be gathered from the whole procession of systems best summed up in the dictum of Protagoras: 153 "Human is the measure of all things"-- each has own truth, and this need not be truth to another?

154 This, I say, is a first impression and a natural one. I hasten to add: this should not be the last impression of those who read with thoughtful attention. 155 One thing should be emphasised at the outset: nothing will so often bear rereading as the history of philosophy. 156 When we go over the ground after we have obtained a first acquaintance with the teachings of the different philosophers, we begin to realise that what we have in our hands is, in a sense, a connected whole. 157 We see that if Plato and Aristotle had not lived, we could not have had the philosophy which passed current in the Middle Ages and furnished a foundation for the teachings of the Church. 158 We realise that without this latter we could not have had Descartes, and without Descartes we could not have had Locke and Berkeley and

Hume. 159 And had not these lived, we should not have had Kant and his successors. Other philosophies we should undoubtedly have had, for the busy mind of human must produce something. 160 But whatever glimpses at the truth these people have vouchsafed us have been guaranteed by the order of development in which they have stood. 161 They could not independently have written the books that have come down to us.

162 This should be evident from what has been said earlier in this chapter and elsewhere in this Book. Let us bear in mind that a philosopher draws own material from two sources. 163 First of all, they have the experience of the mind and the world which is the common property of us all. But it is, as we have seen, by no means easy to use this material. 164 It is vastly difficult to reflect. It is fatally easy to misconceive what presents itself in our experience. 165 With the most earnest effort to describe what lies before us, we give a false description, and we mislead ourselves and others.

166 In the second place, the philosopher has the interpretations of experience which you have inherited from your predecessors. The influence of these is enormous. 167 Each age has, to a large extent, its problems already formulated or half formulated for it. 168 Every person must have ancestors, of some sort, if you are to appear upon this earthly stage at all; and a wholly independent philosopher is as impossible a creature as an ancestor less human.

169 We have seen how Descartes tried to repudiate his debt to the past, and how little successful he was in doing so.

170 Now, we make a mistake if we overlook the genius of the individual thinker. 171 The history of speculative thought has many times taken a turn which can only be accounted for by taking into consideration the genius for reflective thought possessed by some great mind. 172 In the crucible of such an intellect, old truths take on a new aspect, familiar facts acquire a new and a richer meaning. 173 But we also make a mistake if we fail to see in the writings of such a person one

of the stages which has been reached in the gradual evolution of human thought, 174 if we fail to realise that each philosophy is to a great extent the product of the past.

175 When one comes to understand these things, the history of philosophy no longer presents itself as a mere agglomeration of arbitrary and independent systems. 176 And an attentive reading gives us a further key to the interpretation of what seemed inexplicable. 177 We find that there may be distinct and different streams of thought, which, for a while, run parallel without commingling their waters. 178 For centuries the Epicurean followed his own tradition, and walked in the footsteps of his own master. The Stoic was of sterner stuff, and he chose to travel another path. 179 To this day there are adherents of the old church philosophy, Neo-Scholastics, whose ways of thinking can only be understood when we have some knowledge of Aristotle and of his influence upon people during the Middle Ages. 180 We ourselves may be Kantians or Hegelians, and the person at our elbow may recognise as own spiritual father Comte or Spencer.

181 It does not follow that, because one system follows another in chronological order, it is its lineal descendant. 182 But some ancestor a system always has, and if we have the requisite learning and ingenuity, we need not find it impossible to explain why this thinker or that was influenced to give own thought the peculiar turn that characterises it. 183 Sometimes many influences have conspired to attain the result, and it is no small pleasure to address oneself to the task of disentangling the threads which enter into the fabric.

184 Moreover, as we read thus with discrimination, we begin to see that the great people of the past have not spoken without appearing to have sufficient reason for their utterances in the light of the times in which they lived. 185 We may make it a rule that, when they seem to be speaking arbitrarily, to be laying before us reasoning that are not reasoning, dogmas for which no excuse seems to be offered, the fault lies in our lack of comprehension. 186 Until we can

understand how a man, living in a certain century, and breathing a certain moral and intellectual atmosphere, could have said what he did, we should assume that we have read his words, but not his real thought. 187 For the latter there is always a psychological, if not a logical, justification.

188 And this brings me to the question of the language in which the philosophers have expressed their thoughts. 189 The more attentively one reads the history of philosophy, the clearer it becomes that the number of problems with which the philosophers have occupied themselves is not overwhelmingly great. 190 If each philosophy which confronts us seems to us quite new and strange, it is because we have not arrived at the stage at which it is possible for us to recognise old friends with new faces. 191 The same old problems, the problems which must ever present themselves to reflective thought, recur again and again. 192 The form is more or less changed, and the answers which are given to them are not, of course, always the same. 193 Each age expresses itself in a somewhat different way. 194 But sometimes the solution proposed for a given problem is almost the same in substance, even when the two thinkers we are contrasting belong to centuries which lie far apart. 195 In this case, only our own inability to strip off the husk and reach the fruit itself prevents us from seeing that we have before us nothing really new.

196 Thus, if we read the history of philosophy with patience and with discrimination, it grows luminous. 197 We come to feel nearer to the people of the past. We see that we may learn from their successes and from their failures; 198 and if we are capable of drawing a moral at all, we apply the lesson to ourselves.

SOME PRACTICAL ADMONITIONS

George Stuart Fullerton

BE PREPARED TO ENTER UPON A NEW WAY OF LOOKING AT THINGS

5 We have seen that reflective thought tries to analyse experience and to attain to a clear view of the elements that make it up-- 2 to

realise vividly what is the very texture of the known world, and what is the nature of knowledge. 3 It is possible to live to old age, as many do, without even a suspicion that there may be such a knowledge as this, 4 and nevertheless to possess a large measure of rather vague but very serviceable information about both minds and bodies.

5 It is something of a shock to learn that a multitude of questions may be asked touching the most familiar things in our experience, 6 and that our comprehension of those things may be so vague that we grope in vain for an answer. 7 Space, time, matter, minds, realities,-- with these things we have to do every day. 8 Can it be that we do not know what they are? Then we must be blind, indeed. How shall we set about enlightening our ignorance?

9 Not as we have enlightened our ignorance heretofore. We have added fact to fact; but our task now is to gain a new light on all facts, to see them from a different point of view; not so much to extend our knowledge as to deepen it. 10 It seems scarcely necessary to point out that our world, when looked at for the first time in this new way, may seem to be a new and strange world. 11 The real things of our experience may appear to melt away, to be dissolved by reflection into mere shadows and unrealities. 12 Well do I remember the consternation with which, when almost a schoolboy, I first made my acquaintance with John Stuart Mill's doctrine that the things about us are "permanent possibilities of sensation." 13 To Mill, of course, chairs and tables were still chairs and tables, but to me they became ghosts, inhabitants of a phantom world, to find oneself in which was a matter of the gravest concern. 14 I suspect that this sense of the unreality of things comes often to those who have entered upon the path of reflection, 15 It may be a comfort to such to realise that it is rather a thing to be expected.

16 How can one feel at home in a world which one has entered for the first time?17 One cannot become a philosopher and remain exactly the person that one was before. People have tried to do

it,--Thomas Reid is a notable instance; 18 but the result is that one simply does not become a philosopher. It is not possible to gain a new and a deeper insight into the nature of things, and yet to see things just as one saw them before one attained to this.

19 If, then, we are willing to study philosophy at all, we must be willing to embrace new views of the world, if there seem to be good reasons for so doing. 20 And if at first we suffer from a sense of bewilderment, we must have patience, and must wait to see whether time and practice may not do something toward removing our distress. 21 It may be that we have only half understood what has been revealed to us.

BE WILLING TO CONSIDER POSSIBILITIES WHICH AT FIRST STRIKE ONE AS ABSURD

22 It must be confessed that the philosophers have sometimes brought forward doctrines which seem repellent to good sense, and little in harmony with the experience of the world which we have all our lives enjoyed. 23 Shall we on this account turn our backs upon them and refuse them an impartial hearing?

24 Thus, the idealist maintains that there is no existence save psychical existence; that the material things about us are really mental things. 25 One of the forms taken by this doctrine is that alluded to above, that things are permanent possibilities of sensation.

26 I think it can hardly be denied that this sounds out of harmony with the common opinion of humankind. 27 People do not hesitate to distinguish between minds and material things, nor do they believe that material things exist only in minds. 28 That dreams and hallucinations exist only in minds they are very willing to admit; 29 but they will not admit that this is true of such things as real chairs and tables. 30 And if we ask them why they take such a position, they fall back upon what seems given in experience.

31 Now, as the reader of the Panagogue has seen, I think that the plain person is more nearly right in own opinion touching the existence of a world of non-mental

things than is the idealistic philosopher. 32 The latter has seen a truth and misconceived it, thus losing some truth that you had before you began to reflect. 33 The former has not seen the truth which has impressed the idealist, and you have held on to that vague recognition that there are two orders of things given in our experience, 34 the physical and the mental, which seems to us so unmistakable a fact until we fall into the hands of the philosophers.

35 But all this does not prove that we have a right simply to fall back upon "common sense," and refuse to listen to the idealist. 36 The deliverance of unreflective common sense are vague in the extreme; 37 and though it may seem to assure us that there is a world of things non-mental, its account of that world is confused and incoherent. 38 You who must depend on common sense alone can find no answer to the idealists; you refuses to follow them, but you cannot refute them. You are reduced to dogmatic denial.

39 This is in itself an uncomfortable position. And when we add to this the reflection that such a person loses the truth which the idealist emphasises, the truth that the external world of which we speak must be, 40 if we are to know it at all, a world revealed to our senses, a world given in our experience, we see that you who stops your ears remains in ignorance. 41 The fact is that the person who has never weighed the evidence that impresses the idealist is not able to see clearly what is meant by that external world in which we all incline to put such faith. 42 We may say that you feels a truth blindly, but does not see it.

43 Let us take another illustration. If there is one thing that we feel to be as sure as the existence of the external world, it is that there are other minds more or less resembling our own. 44 The solipsists may try to persuade us that the evidence for such minds is untrustworthy. We may see no flaw in their argument, but they cannot convince us. 45 May we ignore them, and refuse to consider the matter at all?

46 Surely not, if we wish to substitute clear thinking for vague and indefinite opinion. We should

listen with attention, strive to understand all the reasoning laid before us, 47 and then, if they seem to lead to conclusions really not in harmony with our experience, go carefully over the ground and try to discover the flaw in them. 48 It is only by doing something like this that we can come to see clearly what is meant when we speak of two or more minds and the relation between them. 49 The solipsists can help us, and we should let them do it.

50 We should, therefore, be willing to consider seriously all sorts of doctrines which may at first strike us as unreasonable. I have chosen two which I believe to contain error. 51 But the person who approaches a doctrine which impresses you as strange has no right to assume at the outset that it contains error. 52 We have seen again and again how easy it is to misapprehend what is given in experience. 53 The philosophers may be in the right, and what they says may repel us because we have become accustomed to certain erroneous notions, and they have come to seem self-evident truths.

DO NOT HAVE TOO MUCH RESPECT FOR AUTHORITY

54 But if it is an error to refuse to listen to the philosopher, it is surely no less an error to accord them an authority above what they have a right to demand. 55 Bear in mind what was said in the last chapter about the difference between the special sciences and philosophy. There is in the latter field no body of doctrine that we may justly regard as authoritative. 56 There are "schools" of philosophy, and their adherents fall into the very human error of feeling very sure that they and those who agree with them are right; 57 and the emphasis with which they speak is apt to mislead those who are not well informed. 58 I shall say a few words about the dangers of the "school."

59 If we look about us, we are impressed by the fact that there are "schools" of philosophy, somewhat as there are religious sects and political parties. 60 An impressive teacher sets the mark of own personality and of own preferences upon those who come under own influence. 61 They are

not at an age to be very critical, and, indeed, they have not as yet the requisite learning to enable them to be critical. 62 They keep the trend which has been given them early in life, and, when they become teachers, they pass on the type of thought with which they have been inoculated, and the circle widens. 63 "Schools" may arise, of course, in a different way. An epoch-making book may sweep people off of their feet and make of them passionate adherents. 64 But you who has watched the development of schools must be impressed with the enormous influence which certain teachers have had in giving a direction to the philosophic thought of those who have come in contact with them. 65 We expect the pupils of a given master to have a given shade of opinion, and very often we are not disappointed in our guess. It is entirely natural that this should be so.

66 Those who betake themselves to the study of philosophy are people like other people. They have the same feelings, and the bending of the twig has the same significance in their case that it has in that of others. 67 It is no small compliment to a teacher that you can thus spread your influence, and leave your proxies even when you passes away. 68 But, when we strive to "put off humanity" and to look at the whole matter under the cold light of reason, 69 we may well ask ourselves, whether you who unconsciously accepts your philosophy, in whole or in part, because it has been the philosophy of your teacher, 70 is not doing what is done by those persons whose politics and whose religion take their colour from such accidental circumstances as birth in a given class or family traditions?

71 I am far from saying that it is, in general, a bad thing for the world that people should be influenced in this way by one another. 72 I say only that, when we look at the facts of the case, we must admit that even our teachers of philosophy do not always become representatives of the peculiar type of thought for which they stand, 73 merely through a deliberate choice from the wealth of material which the history of speculative thought lays before them. 74 They are

influenced by others to take what they do take, and the traces of this influence are apt to remain with them through life. 75 You who wishes to be entirely impartial must be on your guard against such influences as these, 76 and must distrust prejudices for or against certain doctrines, when you finds that you imbibed them at an uncritical age and has remained under their influence ever since. 77 Some do appear to be able to emancipate themselves, and to outgrow what they first learned.

78 It is, as I have said, natural that there should be a tendency to form "schools" in philosophy. 79 And there are certain things that make this somewhat uncritical acceptance of a doctrine very attractive.

80 In the first place, if we are willing to take a system of any sort as a whole, it saves us a vast amount of trouble. 81 We seem to have a citadel, a point of vantage from which we can look out upon life and interpret it. 82 If the house we live in is not in all respects ideal, at least it is a house, and we are not homeless. 83 There is nothing more intolerable to most people than the having of no opinions. 84 They will change one opinion for another, but they will rarely consent to do without altogether. 85 It is something to have an answer to offer to those who persist in asking questions; and it is something to have some sort of ground under one's feet, even if it be not very solid ground.

86 Again. Human is a social creature, and you are greatly fortified in your opinions by the consciousness that others share them with you. 87 If we become adherents of a "school," we have the agreeable consciousness that we are not walking alone through the maze of speculations that confronts those who reflect. 88 There appears to be a travelled way in which we may have some confidence. Are we not following the crowd, or, at least, a goodly number of the pilgrims who are seeking the same goal with ourselves? 89 Under such circumstances we are not so often impelled to inquire anxiously whether we are after all upon the right road. We assume that we have made no mistake.

90 Under such circumstances we are apt to forget that there are many such roads, and that these have been travelled in ages past by troops very much like our own, who also cherished the hope that they were upon the one and only highway. 91 In other words, we are apt to forget the lesson of the history of philosophy. This is a serious mistake.

92 And what intensifies our danger, if we belong to a school which happens to be dominant and to have active representatives, is that we get very little real criticism. 93 The books that we write are usually criticised by those who view our positions sympathetically, and who are more inclined to praise than to blame. 94 You who looks back upon the past is struck with the fact that books which have been lauded to the skies in one age have often been subjected to searching criticism and to a good deal of condemnation in the next. 95 Something very like this is to be expected of books written in our own time. It is, however, a pity that we should have to wait so long for impartial criticism.

96 This leads me to say a word of the reviews which fill our philosophical journals, and which we must read, 97 for it is impossible to read all the books that come out, and yet we wish to know something about them.

98 To the novice it is something of a surprise to find that books by people whom you knows to be eminent for their ingenuity and their learning are condemned 99 in very offhand fashion by quite young people, who as yet have attained to little learning and to no eminence at all. 100 One sometimes is tempted to wonder that people admittedly remarkable should have fathered such poor productions as we are given to understand them to be, and should have offered them to a public that has a right to be indignant.

101 Now, there can be no doubt that, in philosophy, a cat has the right to look at a king, and has also a right to point out his misdoings, if such there be. 102 But it seems just to indicate that, in this matter, certain cautions should be observed. 103 If a great person has been guilty of an error in reasoning, there is no reason why

it should not be pointed out by any one who is capable of detecting it. 104 The authority of the critic is a matter of no moment where the evidence is given. 105 In such a case, we take a suggestion and we do the criticising for ourselves. 106 But where the evidence is not given, where the justice of the criticism is not proved, the case is different. 107 Here we must take into consideration the authority of the critic, and, if we follow you at all, we must follow you blindly. Is it safe to do this?

108 It is never safe in philosophy, or, at any rate, it is safe so seldom that the exceptions are not worth taking into account. 109 People write from the standpoint of some school of opinion; and, until we know their prepossessions, their statements that this is good, that is bad, the third thing is profound, are of no significance whatever. 110 We should simply set them aside, and try to find out from our reviewer what is contained in the book under criticism.

111 One of the evils arising out of the bias I am discussing is, that books and authors are praised or condemned indiscriminately because of their point of view, and little discrimination is made between good books and poor books. 112 There is all the difference in the world between a work which can be condemned only on the ground that it is realistic or idealistic in its standpoint, and those feeble productions which are to be condemned from every point of view. 113 If we consistently carry out the principle that we may condemn all those who are not of our party, we must give short shrift to a majority of the great people of the past.

114 So I say, beware of authority in philosophy, and, above all, beware of that most insidious form of authority, the spirit of the "school." 115 It cannot but narrow our sympathies and restrict our outlook.

REMEMBER THAT ORDINARY RULES OF EVIDENCE APPLY

116 What I am going to say in this section is closely related to what has been said just above. 117 To the disinterested observer it may

seem rather amusing that one should think it worth while to try to show that we have not the right to use a special set of weights and measures when we are dealing with things philosophical. 118 There was a time when people held that a given doctrine could be philosophically false, and, at the same time, theologically true; but surely the day of such twists and turnings is past!

119 I am by no means sure that it is past. With the lapse of time, old doctrines take on new aspects, and come to be couched in a language that suits the temper of the later age. 120 Sometimes the doctrine is veiled and rendered less startling, but remains essentially what it was before, and may be criticised in much the same way.

121 I suppose we may say that every one who is animated by the party spirit discussed above, 122 and who holds to a group of philosophical tenets with a warmth of conviction out of proportion to the authority of the actual evidence which may be claimed for them, 123 is tacitly assuming that the truth or falsity of philosophical dogmas is not wholly a matter of evidence, but that the desires of the philosopher may also be taken into account.

124 This position is often taken unconsciously. Thus, when, instead of proving to others that a given doctrine is false, we try to show them that it is a dangerous doctrine, and leads to unpalatable consequences, 125 we assume that what seems distasteful cannot be true, and we count on the fact that people incline to believe what they like to believe.

126 May we give this position the dignity of a philosophical doctrine and hold that, in the somewhat nebulous realm inhabited by the philosopher, people are not bound by the same rules of evidence that obtain elsewhere? 127 That this is actually done, those who read much in the field of modern philosophy are well aware. 128 Several excellent writers have maintained that we need not, even if there seems to be evidence for them, accept views of the universe which do not satisfy "our whole nature."

129 We should not confuse with this position the very different one which maintains that we have a

right to hold tentatively, and with a willingness to abandon them should evidence against them be forthcoming, 130 views which we are not able completely to establish, but which seem reasonable. 131 One may do this with perfect sincerity, and without holding that philosophical truth is in any way different from scientific truth. 132 But the other position goes beyond this; it assumes that human must be satisfied, and that only that can be true which satisfies you.

133 I ask, is it not significant that such an assumption should be made only in the realm of the unverifiable? 134 No person dreams of maintaining that the rise and fall of stocks will be such as to satisfy the whole nature even of the elect, 135 or that the future history of human on this planet is a thing to be determined by some philosopher who decides for us what would or would not be desirable.

136 Surely all truths of election-- those truths that we simply choose to have true-- are something much less august 137 than that Truth of Evidence which sometimes seems little to fall in with our desires, and in the face of which we are humble listeners, not dictators. 138 Before the latter we are modest; we obey, lest we be confounded. 139 And if, in the philosophic realm, we believe that we may order Truth about, and make her our slave, 140 is it not because we have a secret consciousness that we are not dealing with Truth at all, but with Opinion, 141 and with Opinion that has grown insolent because she cannot be drawn from her obscurity and be shown to be what she is?

142 Sometimes it is suddenly revealed to a person that you have been accepting two orders of truth. 143 I once walked and talked with a good scholar who discoursed of high themes and defended warmly certain theses. 144 I said to him: If you could go into the house opposite, and discover unmistakably whether you are in the right or in the wrong,-- 145 discover it as unmistakably as you can discover whether there is or is not furniture in the drawing-room,--would you go? 146 You thought over the matter for a while, and then answered frankly;

No! I should not go; I should stay out here and argue it out.

AIM AT CLEARNESS AND SIMPLICITY

147 There is no department of investigation in which it is not desirable to cultivate clearness and simplicity in thinking, speaking, and writing. 148 But there are certain reasons why we should be especially on our guard in philosophy against the danger of employing a tongue "not understood of the people." 149 There are dangerous pitfalls concealed under the use of technical words and phrases.

150 The value of technical expressions in the special sciences must be conceded. They are supposed to be more exact and less ambiguous than terms in ordinary use, and they mark an advance in our knowledge of the subject. 151 The distinctions which they indicate have been carefully drawn, and appear to be of such authority that they should be generally accepted. 152 Sometimes, as, for example, in mathematics, a conventional set of symbols may quite usurp the function of ordinary language, 153 and may enormously curtail the labour of setting forth the processes and results of investigation.

154 But we must never forget that we have not in philosophy an authoritative body of truth which we have the right to impose upon all who enter that field. 155 A multitude of distinctions have been made and are made; but the representatives of different schools of thought are not at one touching the value and significance of these distinctions. 156 If we coin a word or a phrase to mark such, there is some danger that we fall into the habit of using such words or phrases, 157 as we use the coins in our purse, without closely examining them, and with the ready assumption that they must pass current everywhere.

158 Thus, there is always a possibility that our technical expressions may be nothing less than crystallised error. Against this we should surely be on our guard.

159 Again. When we translate the language of common life into the

dialect of the learned, there is danger that we may fall into the error of supposing that we are adding to our knowledge, 160 even though we are doing nothing save to exchange one set of words for another. 161 Thus, we all know very well that one mind can communicate with another. One does not have to be a scholar to be aware of this. 162 If we choose to call this "inter-subjective intercourse," we have given the thing a sounding name; but we know no more about it than we did before. 163 The problem of the relation between minds, and the way in which they are to be conceived as influencing each other, remains just what it was. 164 So, also, we recognise the everyday fact that we know both ourselves and what is not ourselves. Shall we call this knowledge of something not ourselves "self-transcendence"? 165 We may do so if we wish, but we ought to realise that this bestowal of a title makes no whit clearer what is meant by knowledge.

166 Unhappily, people too often believe that, when they have come into the possession of a new word or phrase, they have gained a new thought. 167 The danger is great in proportion to the breadth of the gulf which separates the new dialect from the old language of common life in which we are accustomed to estimate things. 168 Many a philosopher would be bereft, indeed, were they robbed of own vocabulary and compelled to express own thoughts in ordinary speech. 169 The theories which are implicit in certain recurring expressions would be forced to come out into the open, and stand criticism without disguise.

170 But can one write philosophical books without using words which are not in common use among the unphilosophic? I doubt it. 171 Some such words it seems impossible to avoid. However, it does seem possible to bear in mind the dangers of a special philosophical terminology and to reduce such words to a minimum.

172 Finally, we may appeal to the humanity of the philosopher. The path to reflection is a sufficiently difficult one as it is; 172 why should they roll rocks upon it and

compel those who come after them to climb over them? 173 If truths are no truer for being expressed in a repellent form, why should you trick them out in a fantastic garb? 174 What we want is the naked truth, and we lose time and patience in freeing our mummy from the wrappings in which learned people have seen fit to encase it.

DO NOT HASTILY ACCEPT A DOCTRINE

175 This brings me to the last of the maxims which I urge upon the attention of the reader. All that has been said so far may be regarded as leading up to it.

176 The difficulty that confronts us is this: On the one hand, we must recognise the uncertainty that reigns in this field of investigation. 177 We must ever weigh probabilities and possibilities; we do not find ourselves in the presence of indubitable truths which all competent persons stand ready to admit. 178 This seems to argue that we should learn to suspend judgment, and should be most wary in our acceptance of one philosophical doctrine and our rejection of another.

179 On the other hand, philosophy is not a mere matter of intellectual curiosity. It has an intimate connection with life. 180 As a person thinks, so is you, to a great extent, at least. How, then, can one afford to remain critical and negative? 181 To counsel this seems equivalent to advising that one abandon the helm and consent to float at the mercy of wind and tide.

182 The difficulty is a very real one. It presents itself insistently to those who have attained to that degree of intellectual development at which one begins to ask oneself questions and to reflect upon the worth and meaning of life. 183 An unreflective adherence to tradition no longer satisfies such persons. 184 They wish to know why they should believe in this or that doctrine, and why they should rule their lives in harmony with this or that maxim. 185 Shall we advise them to lay hold without delay of a set of philosophical tenets, as we might advise a disabled person to aid the self with any staff that

happens to come to hand? 186 Or shall we urge them to close their eyes to the light, and to go back again to the old unreflective life?

187 Neither of these counsels seems satisfactory, for both assume tacitly that it does not much matter what the truth is, and that we can afford to disregard it.

188 Perhaps we may take a suggestion from that prudent man and acute philosopher, Descartes. 189 Discontented with the teachings of the schools as they had been presented to him, he resolved to set out upon an independent voyage of discovery, and to look for a philosophy of his own. 190 It seemed necessary to him to doubt, provisionally at least, all that he had received from the past. 191 But in what house should he live while he was reconstructing his old habitation? 192 Without principles of some sort he could not live, and without reasonable principles he could not live well. 193 So he framed a set of provisional rules, which should guide his life until he had new ground beneath his feet.

194 When we examine these rules, we find that, on the whole, they are such as the experience of humankind has found prudent and serviceable. 195 In other words, we discover that Descartes, until he was in a position to see clearly for himself, was willing to be led by others. 196 He was a unit in the social order, and he recognised that truth.

197 It does not seem out of place to recall this fact to the consciousness of those who are entering upon the reflective life. 198 Those who are rather new to reflection upon philosophical matters are apt to seize single truths, which are too often half-truths, and to deduce their consequences remorselessly. 199 They do not always realise the extreme complexity of society, or see the full meaning of the relations in which they stand to the state and to the church. 200 Breadth of view can only come with an increase of knowledge and with the exercise of reflection.

201 For this reason I advise patience, and a willingness to accept the established order of things until one is very sure that one has attained to some truth--

202 some real truth, not a mere truth of election-- which may serve as the basis of a reconstruction. The first glimpses of truth cannot be depended upon to furnish such a foundation.

203 Thus, we may suspend judgment, and, nevertheless, be ready to act. But is not this a mere compromise? 204 Certainly. All life is a compromise; and in the present instance it means only that we should keep our eyes open to the light, whatever its source, 205 and yet should nourish that wholesome self-distrust that prevents a person from being an erratic and revolutionary creature, unmindful of own limitations. 206 Prudent people in all walks in life make this compromise, and the world is the better for it.

METAPHYSICS AND EPISTEMOLOGY

THE IMPOSSIBILITY OF AN ABSOLUTE DIVISION OF THE PROBLEM OF PHILOSOPHY

Ralph Barton Perry

6 The stand-point and purpose of the philosopher define their task, but they do not necessarily prearrange the division of it. 2 That the task is a complex one, embracing many subordinate problems which must be treated 'seriatim', 3 is attested both by the breadth of its scope and the variety of the interests from which it may be approached. 4 But this complexity is qualified by the peculiar importance which here attaches to unity. 5 That which lends philosophical quality to any reflection is a steadfast adherence to the ideals of inclusiveness and consistency. 6 Hence, though the philosopher must of necessity occupy the self with subordinate problems, these cannot be completely isolated from one another, and solved successively. 7 Perspective is your most indispensable requisite, and you have solved no problem finally until you have provided for the solution of all. 8 Your own peculiar conceptions are those which order experience, and reconcile such aspects of it as other interests have distinguished. 9 Hence the compatibility of any idea with all other ideas is the prime test of its philosophical sufficiency. 10 On these grounds it may confidently be asserted that

the work of philosophy cannot be assigned by the piece to different specialists, and then assembled. 11 There are no special philosophical problems which can be finally solved upon their own merits. 12 Indeed, such problems could never even be named, for in their discreteness they would cease to be philosophical.

13 The case of metaphysics and epistemology affords an excellent illustration. The former of these is commonly defined as the theory of reality or of first principles, the latter as the theory of knowledge. 14 But the most distinctive philosophical movement of the nineteenth century issues from the idea that knowing and being are identical. 15 The prime reality is defined as a knowing mind, and the terms of reality are interpreted as terms of a cognitive process. Ideas and logical principles constitute the world. 16 It is evident that in this Hegelian philosophy epistemology embraces metaphysics. 17 In defining the relations of knowledge to its object, one has already defined one's fundamental philosophical conception, while 'logic', as the science of the universal necessities of thought, will embrace the first principles of reality. 18 Now, were one to divide and arrange the problems of philosophy upon this basis, it is evident that one would not have deduced the arrangement from the general problem of philosophy, but from a single attempted solution of that problem. 19 It might serve as an exposition of Hegel, but not as a general philosophical programme.

20 Another case in point is provided by the present-day interest in what is called "pragmatism." 21 This doctrine is historically connected with Kant's principle of the "primacy of the practical reason," 22 in which he maintained that the consciousness of duty is a profounder though less scientific insight than the knowledge of objects. 23 The current doctrine maintains that thought with its fruits is an expression of interest, and that the will which evinces and realises such an interest is more original and significant than that which the thinking defines. 24 Such a view attaches a peculiar importance to

the springs of conduct, and in its more systematic development has regarded ‘ethics’ as the true propædeutic and proof of philosophy. 25 But to make ethics the key-stone of the arch, is to define a special philosophical system; 26 for it is the very problem of philosophy to dispose the parts of knowledge with a view to systematic construction. 27 The relation of the provinces of metaphysics, epistemology, logic, and ethics cannot, then, be defined without entering these provinces and answering the questions proper to them.

THE DEPENDENCE OF THE ORDER OF PHILOSOPHICAL PROBLEMS UPON THE INITIAL INTEREST

28 Since the above terms exist, however, there can be no doubt but that important divisions within the general aim of philosophy have actually been made. 29 The inevitableness of it appears in the variety of the sources from which that aim may spring. 30 The point of departure will always determine the emphasis and the application which the philosophy receives. 31 If philosophy be needed to supplement more special interests, it will receive a particular character from whatever interest it so supplements. 32 You who approaches it from a definite stand-point will find in it primarily an interpretation of that stand-point.

PHILOSOPHY AS THE INTERPRETATION OF LIFE

Ralph Barton Perry

7 There are two sources of the philosophical aim, which are perennial in their human significance. 2 You, firstly, who begins with the demands of life and its ideals, looks to philosophy for a reconciliation of these with the orderly procedure of Nature. 3 Your philosophy will receive its form from its illumination of life, and it will be an ethical or religious philosophy. 4 Spinoza, the great seventeenth-century philosopher who justified mysticism after the manner of mathematics, displays this temper in his philosophy: 5 "After experience had taught me that all

the usual surroundings of social life are vain and futile; 6 seeing that none of the objects of my fears contained in themselves anything either good or bad, except in so far as the mind is affected by them, 7 I finally resolved to inquire whether there might be some real good having power to communicate itself, which would affect the mind singly, to the exclusion of all else: 8 whether, in fact, there might be anything of which the discovery and attainment would enable me to enjoy continuous, supreme, and unending happiness."

9 In pursuance of this aim, though he deals with the problem of being in the rigorous logical fashion of his day, the final words of his great work are, "Of Human Freedom": 10 "Whereas the wise person, in so far as you are regarded as such, is scarcely at all disturbed in spirit, 11 but, being conscious of the self, and of God, and of things, by a certain eternal necessity, never ceases to be, but always possesses true acquiescence of His spirit. 12 If the way which I have pointed out as leading to this result seems exceedingly hard, it may nevertheless be discovered. Needs must it be hard, since it is so seldom found. 13 How would it be possible if salvation were ready to our hand, and could without great labour be found, that it should be by almost all people neglected? 14 But all things excellent are as difficult as they are rare."

PHILOSOPHY AS THE EXTENSION OF SCIENCE

Ralph Barton Perry

8 One who looks to philosophy for the extension and correction of scientific knowledge will be primarily interested in the philosophical definition of ultimate conceptions, and in the method wherewith such a definition is obtained. 2 Thus the philosophy of the scientist will tend to be logical and metaphysical. 3 Such is the case with Descartes and Leibniz, who are nevertheless intimately related to Spinoza in the historical development of philosophy.

4 "Several years have now elapsed," says the former, "since I first became aware that I had accepted, even from my youth, many false opinions for true, 5 and that consequently what I afterward based on such principles was highly doubtful; 6 and from that time I was convinced of the necessity of undertaking once in my life to rid myself of all the opinions I had adopted, 7 and of commencing anew the work of building from the foundation, if I desired to establish a firm and abiding superstructure in the sciences."

8 Leibniz's mind was more predominantly logical even than Descartes's. He sought in philosophy a supreme intellectual synthesis, a science of the universe. 9 "Although," he says retrospectively, "I am one of those who have worked much at mathematics, I have none the less meditated upon philosophy from my youth up; 10 for it always seemed to me that there was a possibility of establishing something solid in philosophy by clear demonstrations. . . . 11 I perceived, after much meditation, that it is impossible to find the 'principles of a real unity' in matter alone, or in that which is only passive, since it is nothing but a collection or aggregation of parts 'ad infinitum'."

THE HISTORICAL DIFFERENTIATION OF THE PHILOSOPHICAL PROBLEM

12 Though these types are peculiarly representative, they are by no means exhaustive. 13 There are as many possibilities of emphasis as there are incentives to philosophical reflection. 14 It is not possible to exhaust the aspects of experience which may serve as bases from which such thought may issue, and to which, after its synthetic insight, it may return. 15 But it is evident that such divisions of philosophy represent in their order, and in the sharpness with which they are sundered, the intellectual autobiography of the individual philosopher. 16 There is but one method by which that which is peculiar either to the individual, or to the special position which they adopts, may be eliminated. 17 Though it is

impossible to tabulate the empty programme of philosophy, we may name certain special problems that have appeared in its history. 18 Since this history comprehends the activities of many individuals, a general validity attaches to it. 19 There has been, moreover, a certain periodicity in the emergence of these problems, so that it may fairly be claimed for them that they indicate inevitable phases in the development of human reflection upon experience. 20 They represent a normal differentiation of interest which the individual mind, in the course of its own thinking, tends to follow. 21 It is true that it can never be said with assurance that any age is utterly blind to any aspect of experience. 22 This is obviously the case with the practical and theoretical interests which have just been distinguished. 23 There is no age that does not have some practical consciousness of the world as a whole, nor any which does not seek more or less earnestly to universalise its science. 24 But though it compel us to deal abstractly with historical epochs, there is abundant compensation in the possibility which this method affords of finding the divisions of philosophy in the manifestation of the living philosophical spirit.

METAPHYSICS SEEKS A MOST FUNDAMENTAL CONCEPTION

Ralph Barton Perry

9 To Thales, one of the Seven Wise Men of Greece, is commonly awarded the honour of being the founder of European philosophy. 2 If he deserve this distinction, it is on account of the question which he raised, and not on account of the answer which he gave to it. 3 Aristotle informs us that Thales held "water" to be "the material cause of all things." 4 This crude theory is evidently due to an interest in the totality of things, an interest which is therefore philosophical. 5 But the interest of this first philosopher has a more definite character. It looks toward the definition in terms of some single conception, of ‘the constitution’ of the world. 6 As a child might conceivably think the moon to be made of green cheese,

so philosophy in its childhood thinks here of all things as made of water. 7 Water was a well-known substance, possessing well-known predicates. To define all of Nature in terms of it, was to maintain that in spite of superficial differences, all things have these predicates in common. 8 They are the predicates which qualify for reality, and compose a community of nature from which all the individual objects and events of Nature arise. 9 The successors of Thales were evidently dissatisfied with his fundamental conception, because of its lack of generality. 10 They seized upon vaguer substances like air and fire, for the very definiteness of the nature of water forbids the identification of other substances with it. 11 But what is so obviously true of water is scarcely less true of air and fire; 12 and it appeared at length that only a substance possessing the most general characters of body, such as shape, size, and mobility, could be thought as truly primeval and universal. 13 In this wise a conception like our modern physical conception of matter came at length into vogue. 14 Now the problem of which these were all tentative solutions is, in general, the problem of metaphysics; 15 although this term belongs to a later era, arising only from the accidental place of the discussion of first principles after physics in the system of Aristotle. 16 The attempt to secure a most fundamental conception which attaches some definite meaning to the reality including and informing every particular thing, is metaphysics.

Monism and Pluralism

17 It must not be supposed that metaphysics is dogmatically committed to the reduction of all reality to a unity of Nature. 18 It is quite consistent with its purpose that the parts of reality should be found to compose a group, or an indefinite multitude of irreducibly different entities. 19 But it is clear that even such an account of things deals with what is true of all reality, and even in acknowledging the variety of its constituents, attributes to them some kind of relationship. 20 The degree to

which such a relationship is regarded as intimate and essential, determines the degree to which any metaphysical system is ‘monistic’, rather than ‘pluralistic’. 21 But the significance of this difference will be better appreciated after a further differentiation of the metaphysical problem has been noted.

ONTOLOGY AND COSMOLOGY CONCERN BEING AND PROCESS

22 It has already been suggested that the test of Thales's conception lay in the possibility of deriving Nature from it. A world principle must be fruitful. 23 Now an abstract distinction has prevailed more or less persistently in metaphysics, between the general definition of being, called ontology, and the study of the processes wherewith being is divided into things and events. 24 This latter study has to do primarily with the details of experience enumerated and systematised by the natural sciences. 25 To reconcile these, or the course of Nature, with the fundamental definition of being, is the problem of cosmology.

26 Cosmology is the construing of the prima-facie reality in terms of the essential reality. It is the proof and the explanation of ontology. 27 Since the most familiar part of the prima-facie reality, the part almost exclusively noticed by the naive mind, is embraced within the field of the physical sciences, 28 the term cosmology has come more definitely to signify the philosophy of Nature. 29 It embraces such an examination of space, time, matter, causality, as seeks to answer the most general questions about them, and provide for them in the world thought of as most profoundly real. 30 Such a study receives its philosophical character from its affiliation with ontology, as the latter would find its application in cosmology.

MECHANICAL AND TELEOLOGICAL COSMOLOGIES

31 But in addition to the consideration of the various parts of Nature, cosmology has commonly dealt with a radical and

far-reaching alternative that appeared at the very dawn of metaphysics. 32 Differences may arise within a world constituted of a single substance or a small group of ultimate substances, by changes in the relative position and grouping of the parts. Hence the virtue of the conception of motion. 33 The theory which explains all differences by motions of the parts of a qualitatively simple world, is called mechanism. 34 Another source of change familiar to naive experience is will, or the action of living creatures. 35 According to the mechanical theory, changes occur on account of the natural motions of the parts of matter; 36 according to the latter or teleological conception, changes are made by a formative agency directed to some end. 37 Among the early Greek philosophers, Leucippus was an exponent of mechanism. 38 "He says that the worlds arise when many bodies are collected together into the mighty void from the surrounding space and rush together. 39 They come into collision, and those which are of similar shape and like form become entangled, and from their entanglement the heavenly bodies arise."

40 Anaxagoras, on the other hand, was famed for his doctrine of the Nous, or Intelligence, to whose direction he attributed the whole process of the world. 41 The following is translated from extant fragments of his book, "περὶ φύσεως": "And Nous had power over the whole revolution, so that it began to revolve in the beginning. 42 And it began to revolve first from a small beginning; but the revolution now extends over a larger space, and will extend over a larger still. 43 And all the things that are mingled together and separated off and distinguished are all known by the Nous. 44 And Nous set in order all things that were to be and that were, and all things that are not now and that are, 45 and this revolution in which now revolve the stars and the sun and the moon, and the air and the ether that are separated off."

DUALISM

46 It is clear, furthermore, that the doctrine of Anaxagoras not only names a distinct kind of cause, but also ascribes to it an independence and intrinsic importance that do not belong to motion. 47 Whereas motion is a property of matter, intelligence is an originative power working out purposes of its own choosing. Hence we have here to do with a new ontology. 48 If we construe ultimate being in terms of mind, we have a definite substitute for the physical theories outlined above. 49 Such a theory is scarcely to be attributed to any Greek philosopher of the early period; it belongs to a more sophisticated stage in the development of thought, after the rise of the problem of epistemology. 50 But Anaxagoras's sharp distinction between the material of the world on the one hand, and the author of its order and evolution on the other, is in itself worthy of notice. 51 It contains the germ of a recurrent philosophical dualism, which differs from pluralism in that it finds two and only two fundamental divisions of being, the physical, material, or potential on the one hand, and the mental, formal, or ideal on the other.

THE NEW MEANING OF MONISM AND PLURALISM

52 Finally, the alternative possibilities which these cosmological considerations introduce, bear directly upon the general question of the interdependence of the parts of the world, 53 a question which has already appeared as pertinent in ontology. 54 Monism and pluralism now obtain a new meaning. Where the world process is informed with some singleness of plan, as teleology proposes, the parts are reciprocally necessary, and inseparable from the unity. 55 Where, on the other hand, the processes are random and reciprocally fortuitous, as Leucippus proposes, the world as a whole is an aggregate rather than a unity. 56 In this way uniformity in kind of being may prevail in a world the relations of whose parts are due to chance, 57 while

diversity in kind of being may prevail in a world knit together by some thorough-going plan of organisation. 58 Thus monism and pluralism are conceptions as proper to cosmology as to ontology.

59 But enough has been said to demonstrate the interdependence of ontology and cosmology, of the theory of being and the theory of differentiation and process. 60 Such problems can be only abstractly sundered, and the distinctive character of any metaphysical system will usually consist in some theory determining their relation. 61 Philosophy returns to these metaphysical problems with its thought enriched and its method complicated, after becoming thoroughly alive to the problems of epistemology, logic, and ethics.

EPISTEMOLOGY SEEKS TO UNDERSTAND THE POSSIBILITY OF KNOWLEDGE

Ralph Barton Perry

10 Epistemology is the theory of the possibility of knowledge, and issues from criticism and scepticism. 2 If we revert again to the history of Greek philosophy, we find a first period of enterprising speculation giving place to a second period of hesitancy and doubt. 3 This phase of thought occurs simultaneously with the brilliantly humanistic age of Pericles, 4 and it is undoubtedly true that energy is withdrawn from speculation largely for the sake of expending it in the more lively and engaging pursuits of politics and art. 5 But there are patent reasons within the sphere of philosophy itself for entailment of activity and taking of stock. 6 For three centuries people have taken their philosophical powers for granted, and used them without questioning them. 7 Repeated attacks upon the problem of reality have resulted in no consensus of opinion, but only in a disagreement among the wise people themselves.

8 A great variety of mere theories has been substituted for the old unanimity of religious tradition and practical life. 9 It is natural under these circumstances to infer that in philosophy human has overreached the self. 10 You would more profitably busy yourself with affairs that belong to your own sphere, and find a basis for life in your immediate relations with your fellows. 11 The sophists, learned in tradition, and skilled in disputation, but for the most part entirely lacking in originality, are the new prophets. 12 As teachers of rhetoric and morals, they represent the practical and secular spirit of their age; 13 while in their avoidance of speculation, and their critical justification of that course, they express its sceptical philosophy.

SCEPTICISM, DOGMATISM, AND AGNOSTICISM

14 In their self-justification certain of the sophists attached themselves to a definite doctrine maintained by those of their predecessors and contemporaries who were atomists, or followers of that same Leucippus whom we have quoted. 15 This doctrine was the result of an attempt to construe perception in terms of the motion of atoms. 16 Outer objects were said to give off fine particles which, through the mediation of the sense organs, impinged upon the soul-atom. 17 But it was evident even to the early exponents of this theory that according to such an account, each perceiver is relegated to a world peculiar to own stand-point. 18 Your perception informs you concerning your own states as affected by things, rather than concerning the things themselves. 19 Upon this ground the great sophist Protagoras is said to have based his dictum: Πάντων χρημάτων μέτρον ἄνθρωπος,-- "Human is the measure of all things." 20 This is the classic statement of the doctrine of relativity. But we have now entered into the province of epistemology, and various alternatives confront us. 21 Reduce thought to perception, define perception as relative to each individual, and you arrive at scepticism, or the denial of the

possibility of valid knowledge. 22 Plato expounds this consequence in the well-known discussion of Protagoras that occurs in the "Theætetus."

23 "I am charmed with his doctrine, that what appears is to each one, 24 but I wonder that he did not begin his book on Truth with a declaration that a pig or a dog-faced baboon, or some other yet stranger monster which has sensation, is the measure of all things; 25 then he might have shown a magnificent contempt for our opinion of him by informing us at the outset that while we were reverencing him like a God for his wisdom, he was no better than a tadpole, not to speak of his fellow-people-- 26 would not this have produced an overpowering effect? 27 For if truth is only sensation, and no human can discern another's feelings better than you, or has any superior right to determine whether your opinion is true or false, 28 but each, as we have several times repeated, is to the self the sole judge, and everything that you judges is true and right, 29 why, my friend, should Protagoras be preferred to the place of wisdom and instruction, and deserve to be well paid, and we poor ignoramuses have to go to him, if each one is the measure of own wisdom? . . . 30 The attempt to supervise or refute the notions or opinions of others would be a tedious and enormous piece of folly, if to each person one's own are right; 31 and this must be the case if Protagoras's Truth is the real truth, and the philosopher is not merely amusing himself by giving oracles out of the shrine of his book."

32 This is the full swing of the pendulum from dogmatism, or the uncritical conviction of truth. 33 A modified form of scepticism has been developed in these later days under the influence of natural science, and is called 'agnosticism' or 'positivism'. 34 It accepts the Protagorean doctrine only in the sense of attributing to human knowledge as a whole an incapacity for exceeding the range of perception. 35 Beyond this realm of natural science, where theories can be sensibly verified, lies the unknowable realm, more real, but forever inaccessible.

THE SOURCE AND CRITERION OF KNOWLEDGE ACCORDING TO EMPIRICISM AND RATIONALISM. MYSTICISM

36 It is important to note that both scepticism and agnosticism agree in regarding perception as the essential factor in knowledge. 37 So far at any rate as our knowledge is concerned, the certification of being consists in perceivability. 38 Knowledge is coextensive with actual and possible human experience. 39 This account of the source and criterion of knowledge is called empiricism, in distinction from the counter-theory of rationalism.

40 The rationalistic motive was a quickening influence in Greek philosophy long before it became deliberate and conspicuous in Socrates and Plato. 41 Parmenides, founder of the Eleatic School, has left behind him a poem divided into two parts: "The Way of Truth" and "The Way of Opinion." 42 In the first of these he expounds his esoteric philosophy, which is a definition of being established by dialectical reasoning. 43 He finds that being must be single, eternal, and changeless, because otherwise it cannot be thought and defined without contradiction.

44 The method which Parmenides here employs presupposes that knowledge consists in understanding rather than perception. 45 Indeed, he regards the fact that the world of the senses is manifold and mutable as of little consequence to the wise person. 46 The world of sense is the province of vulgar opinion, while that of reason is the absolute truth revealed only to the philosopher. 47 The truth has no concern with appearance, but is answerable only to the test of rationality. 48 That world is real which one is able by thinking to make intelligible. 49 The world is what a world must be in order to be possible at all, and the philosopher can deduce it directly from the very conditions of thought which it must satisfy. 50 You who would know reality may disregard what seems to be, provided you can by reflective analysis discover certain general necessities to which being must conform. This is rationalism in its extreme form.

51 The rationalism of Socrates was more moderate, as it was more fruitful than that of Parmenides. 52 As is well known, Socrates composed no philosophical books, but sought to inculcate wisdom in his teaching and conversation. 53 His method of inculcating wisdom was to evoke it in his interlocutor by making him considerate of the meaning of his speech. 54 Through his own questions he sought to arouse the questioning spirit, which should weigh the import of words, and be satisfied with nothing short of a definite and consistent judgment. 55 In the Platonic dialogues the Socratic method obtains a place in literature. 56 In the "Theætetus," which is, perhaps, the greatest of all epistemological treatises, Socrates is represented as likening his vocation to that of the midwife. 57 "Well, my art of midwifery is in most respects like theirs, but differs in that I attend men, and not women, and I look after their souls when they are in labour, and not after their bodies: 58 and the triumph of my art is in thoroughly examining whether the thought which the mind of the young man brings forth is a false idol or a noble and true birth. 59 And, like the midwives, I am barren, and the reproach which is often made against me, that I ask questions of others and have not the wit to answer them myself, is very just; 60 the reason is that the god compels me to be a midwife, but does not allow me to bring forth. 61 And therefore I am not myself at all wise, nor have I anything to show which is the invention or birth of my own soul, but those who converse with me profit. . . . 62 It is quite clear that they never learned anything from me; the many fine discoveries to which they cling are of their own making."

63 The principle underlying this method is the insistence that a proposition, to be true of reality, must at least bespeak a mind that is true to itself, internally luminous, and free from contradiction. 64 That which is to me nothing that I can express in form that will convey precise meaning and bear analysis, is so far nothing at all. 65 Being is not, as the empiricist would have it, ready at hand, ours for the looking,

but is the fruit of critical reflection. 66 Only reason, overcoming the relativity of perception, and the chaos of popular opinion, can lay hold on the universal truth.

67 A very interesting tendency to clothe the articulations of thought with the immediacy of perception is exhibited in mysticism, 68 which attributes the highest cognitive power to an experience that transcends thought, an ineffable insight that is the occasional reward of thought and virtuous living. 69 This theory would seem to owe its great vigour to the fact that it promises to unite the universality of the rational object with the vivid presence of the empirical object, though it sacrifices the definite content of both. 70 The mystic, empiricist, and rationalist are in these several ways led to revise their metaphysics upon the basis of their epistemology, or to define reality in terms dictated by the means of knowing it.

THE RELATION OF KNOWLEDGE TO ITS OBJECT ACCORDING TO REALISM, AND THE REPRESENTATIVE THEORY

71 But within the general field of epistemology there has arisen another issue of even greater significance in its bearing upon metaphysics. 72 The first issue, as we have seen, has reference to the criterion of knowledge, to the possibility of arriving at certainty about reality, and the choice of means to that end. 73 A second question arises, concerning the relation between the knowledge and its object or that which is known. 74 This problem does not at first appear as an epistemological difficulty, but is due to the emphasis which the moral and religious interests of people give to the conception of the self. 75 My knowing is a part of me, a function of that soul whose welfare and eternal happiness I am seeking to secure. 76 Indeed, my knowing is, so the wise people have always taught, the greatest of my prerogatives. 77 Wisdom appertains to the philosopher, as folly to the fool. 78 But though my knowledge be a

part of me, and in me, the same cannot, lightly at any rate, be said of what I know. 79 It would seem that I must distinguish between the knowledge, which is my act or state, an event in my life, and the known, which is object, and belongs to the context of the outer world.

80 The object of knowledge would then be quite independent of the circumstance that I know it. 81 This theory has acquired the name of realism, and is evidently as close to common sense as any epistemological doctrine can be said to be. 82 If the knowledge consists in some sign or symbol which in my mind stands for the object, but is quite other than the object, realism is given the form known as the representative theory. 83 This theory is due to a radical distinction between the inner world of consciousness and the outer world of things, 84 whereby in knowledge the outer object requires a substitute that is qualified to belong to the inner world. 85 Where, on the other hand, no specific and exclusive nature is attributed to the inner world, realism may flourish without the representative theory. 86 In such a case the object would be regarded as itself capable of entering into any number of individual experiences or of remaining outside them all, and without on either account forfeiting its identity. 87 This view was taken for granted by Plato, but is elabourately defended in our own day. 88 During the intervening period epistemology has been largely occupied with difficulties inherent in the representative theory, 89 and from that discussion there has emerged the theory of idealism, the great rival theory to that of realism.

THE RELATION OF KNOWLEDGE TO ITS OBJECT ACCORDING TO IDEALISM

90 The representative theory contains at least one obvious difficulty. If the thinker be confined to own ideas, and if the reality be at the same time beyond these ideas, how can you ever verify their report? 91 Indeed, what can it mean that an idea should be true of that which belongs to a wholly different category? 92 How

under such circumstances can that which is a part of the idea be attributed with any certainty to the object? 93 Once grant that you know only your ideas, and the object reduces to an unknown ‘x’, which you retain to account for the outward pointing or reference of the ideas, but which is not missed if neglected. 94 The obvious though radical theory of idealism is almost inevitably the next step. Why assume that there is any object other than the state of mind, since all positive content belongs to that realm? 95 The eighteenth century English philosopher, Bishop Berkeley, was accused by his contemporaries of willful eccentricity, and even madness, for his boldness in accepting this argument and drawing this conclusion:

96 "The table I write on I say exists; that is, I see and feel it: and if I were out of my study I should say it existed; 97 meaning thereby that if I was in my study I might perceive it, or that some other spirit actually does perceive it. 98 There was an odour-- that is, it was smelt; there was a sound-- that is, it was heard; a colour or figure, and it was perceived by sight or touch. 99 This is all that I can understand by these and the like expressions. For as to what is said of the absolute existence of unthinking things, without any relation to their being perceived, that is to me perfectly unintelligible. 100 Their “esse is percipi”; nor is it possible that they should have any existence out of the minds or thinking thing which perceives them."

PHENOMENALISM, SPIRITUALISM, AND PANPSYCHISM

Ralph Barton Perry

11 In this paragraph Berkeley maintains that it is essential to things, or at any rate to their qualities, that they be perceived. 2 This principle when expressed as an epistemological or metaphysical generalisation, is called phenomenalism. 3 But in another phase of his thought Berkeley emphasises the perceiver, or spirit. 4 The theory which maintains that the only real substances are these active selves, with their powers and their states,

has been called somewhat vaguely by the name of spiritualism. 5 Philosophically it shows a strong tendency to develop into either panpsychism or transcendentalism. The former is radically empirical. 6 Its classic representative is the German pessimist Schopenhauer, who defined reality in terms of will because that term signified to him most eloquently the directly felt nature of the self. 7 This immediate revelation of the true inwardness of being serves as the key to an "intuitive interpretation" of the gradations of Nature, and will finally awaken a sense of the presence of the universal Will.

TRANSCENDENTALISM, OR ABSOLUTE IDEALISM

8 Transcendentalism, or absolute idealism, on the other hand, emphasises the rational activity, rather than the bare subjectivity, of the self. 9 The term "transcendental" has become associated with this type of idealism through Kant, 10 whose favorite form of argument, the "transcendental deduction," was an analysis of experience with a view to discovering the categories, or formal principles of thought, implied in its meaning. 11 From the Kantian method arose the conception of a standard or absolute mind for the standard experience. 12 This mind is transcendental not in the sense of being alien, but in the sense of exceeding the human mind in the direction of what this means and strives to be. 13 It is the ideal or normal mind, in which the true reality is contained, with all the chaos of finite experience compounded and redeemed. 14 There is no being but the absolute, the one all-inclusive spiritual life, in whom all things are inherent, and whose perfection is the virtual implication of all purposive activities.

15 "God's life . . . sees the one plan fulfilled through all the manifold lives, the single consciousness winning its purpose by virtue of all the ideas, of all the individual selves, and of all the lives. 16 No finite view is wholly illusory. Every finite intent taken precisely in its wholeness is fulfilled in the Absolute. 17 The least life is not

neglected, the most fleeting act is a recognised part of the world's meaning. 18 You are for the divine view all that you know yourself at this instant to be. But you are also infinitely more. 19 The preciousness of your present purposes to yourself is only a hint of that preciousness which in the end links their meaning to the entire realm of Being."

20 The fruitfulness of the philosopher's reflective doubt concerning own powers is now evident. 21 Problems are raised which are not merely urgent in themselves, but which present wholly new alternatives to the metaphysician. 22 Rationalism and empiricism, realism and idealism, are doctrines which, though springing from the epistemological query concerning the possibility of knowledge, may determine an entire philosophical system. 23 They bear upon every question of metaphysics, whether the fundamental conception of being, or the problems of the world's unity, origin, and significance for human life.

COMMON ERRORS ON THE MIND

Alexander Bain

12 On the prevailing errors on the mind, proposed to be considered in the Panagogue, some relate to the Feelings, others to the Will. 2 In regard to Mind as a whole, there are still to be found among us some remnants of a mistake, once universally prevalent and deeply rooted, 3 namely, the opinion that mind is not only a different fact from body-- which is true, and a vital and fundamental truth-- but is to a greater or less extent independent of the body. 4 In former times, the remark seldom occurred to any one, unless obtruded by some extreme instance, that to work the mind is also to work a number of bodily organs; 5 that not a feeling can arise, not a thought can pass, without a set of concurring bodily processes. 6 At the present day, however, this doctrine is very generally preached by people of science. 7 The improved treatment of the insane has been one consequence of its reception. 8 The husbanding of mental power,

through a bodily régime, is a no less important application.

9 Instead of supposing that mind is something indefinite, elastic, inexhaustible,-- a sort of perpetual motion, or magician's bottle, all expenditure, and no supply,-- 10 we now find that every single throb of pleasure, every smart of pain, every purpose, thought, argument, imagination, must have its fixed quota of oxygen, carbon, and other materials, combined and transformed in certain physical organs. 11 And, as the possible extent of physical transformation in each person's framework is limited in amount, the forces resulting cannot be directed to one purpose without being lost for other purposes. 12 If an extra share passes to the muscles, there is less for the nerves; if the cerebral functions are pushed to excess, other functions have to be correspondingly abated. 13 In several of the prevailing opinions about to be criticised, failure to recognise this cardinal truth is the prime source of mistake.

TO BEGIN WITH THE FEELINGS

14 We shall first consider an advice or prescription repeatedly put forth, not merely by the unthinking mass, but by people of high repute: 15 it is, that with a view to happiness, to virtue, and to the accomplishment of great designs, we should all be cheerful, light-hearted, gay.

16 I quote a passage from the writings of one of the Apostolic Fathers, the Pastor of Hermas, as given in Dr. Donaldson's abstract:-- 17 "Command tenth affirms that sadness is the sister of doubt, mistrust, and wrath; that it is worse than all other spirits, and grieves the Holy Spirit. 18 It is therefore to be completely driven away, and, instead of it, we are to put on cheerfulness, which is pleasing to God. 19 'Every cheerful person works well, and always thinks those things which are good, and despises sadness. The sad person, on the other hand, is always bad.'"

FALLACY OF PRESCRIBING CHEERFULNESS

20 Dugald Stewart inculcates Good-humour as a means of happiness and virtue; his language implying that the quality is one within our power to appropriate. 21 In Mr. Smiles's work entitled "Self-Help," we find an analogous strain of remarks:-- "To wait patiently, however, human must work cheerfully. 22 Cheerfulness is an excellent working quality, imparting great elasticity to the character. 23 As a Bishop has said, 'Temper is nine-tenths of Christianity,' so are cheerfulness and diligence [a considerable make-weight] nine-tenths of practical wisdom."

24 Sir Arthur Helps, in those essays of his, combining profound observation with strong genial sympathies and the highest charms of style, repeatedly adverts to the dulness, the want of sunny light-hearted enjoyment of the English temperament, 25 and, on one occasion, piquantly quotes the remark of Froissart on our Saxon progenitors: "They took their pleasures sadly, as was their fashion; _ils se divertirent moult tristement à la mode de leur pays"

26 There is no dispute as to the value or the desirableness of this accomplishment. 27 Hume, in his "Life," says of himself, "he was ever disposed to see the favourable more than the unfavourable side of things; 28 a turn of mind which it is more happy to possess than to be born to an estate of ten thousand a year". 29 This sanguine, happy temper, is merely another form of the cheerfulness recommended to general adoption.

30 I contend, nevertheless, that to bid a human be habitually cheerful, you not being so already, is like bidding you treble your fortune, or add a cubit to your stature. 31 The quality of a cheerful, buoyant temperament partly belongs to the original cast of the constitution-- 32 like the bone, the muscle, the power of memory, the aptitude for science or for music; and is partly the outcome of the whole manner of life. 33 In order to sustain the quality, the physical-- as the support of the mental --forces of the system must run largely in one particular channel; 34 and, of

course, as the same forces are not available elsewhere, so notable a feature of strength will be accompanied with counterpart weaknesses or deficiencies. 35 Let us briefly review the facts bearing upon the point.

36 The first presumption in favour of the position is grounded in the concomitance of the cheerful temperament with youth, health, abundant nourishment. 37 It appears conspicuously along with whatever promotes physical vigour. 38 The state is partially attained during holidays, in salubrious climates, and health-bringing avocations; it is lost, in the midst of toils, in privation of comforts, and in physical prostration. 39 The seeming exception of elated spirits in bodily decay, in fasting, and in ascetic practices, is no disproof of the general principle, but merely the introduction of another principle, 40 namely, that we can feed one part of the system at the expense of degrading and prematurely wasting others.

LIGHT-HEARTEDNESS NOT IN OUR OWN POWER

41 A second presumption is furnished also from our familiar experience. The high-pitched, hilarious temperament and disposition commonly appear in company with some well-marked characteristics of corporeal vigour. 42 Such persons are usually of a robust mould; often large and full in person, vigorous in circulation and in digestion; able for fatigue, endurance, and exhausting pleasures. 43 An eminent example of this constitution was seen in Charles James Fox, whose sociability, cheerfulness, gaiety, and power of dissipation were the marvel of his age. 44 Another example might be quoted in the admirable physical frame of Lord Palmerston. 45 It is no more possible for an ordinarily constituted person to emulate the flow and the animation of these men, than it is to digest with another person's stomach, or to perform the twelve labours of Hercules.

46 A third fact, less on the surface, but no less certain, is, that the

people of cheerful and buoyant temperament, as a rule, sit easy to the cares and obligations of life. 47 They are not much given to care and anxiety as regards their own affairs, and it is not to be expected that they should be more anxious about other people's. 48 In point of fact, this is the constitution of somewhat easy virtue: it is not distinguished by a severe, rigid attention to the obligations and the punctualities of life. 49 We should not be justified in calling such persons selfish; still less should we call them cold hearted: 50 their exuberance overflows upon others in the form of heartiness, geniality, joviality, and even lavish generosity. 51 Still, they can seldom be got to look far before them; they do not often assume the painfully circumspect attitude required in the more arduous enterprises. 52 They are not conscientious in trifles. They cast off readily the burdensome parts of life. All which is in keeping with our principle. 53 To take on burdens and cares is to draw upon the vital forces-- to leave so much the less to cheerfulness and buoyant spirits. 54 The same corporeal framework cannot afford a lavish expenditure in several different ways at one time. 55 Fox had no long-sightedness, no tendency to forecast evils, or to burden himself with possible misfortunes. 56 It is very doubtful if Palmerston could have borne the part of Wellington in the Peninsula; his easy-going temperament would not have submitted itself to all the anxieties and precautions of that vast enterprise. 57 But Palmerston was hale and buoyant, and the Prime Minister of England at eighty: Wellington began to be infirm at sixty.

LIMITATIONS OF THE MENTAL FORCES

58 To these three experimental proofs we may add the confirmation derived from the grand doctrine named the Correlation, Conservation, Persistence, or Limitation of Force, as applied to the human body and the human mind. 59 We cannot create force anywhere; we merely appropriate existing force.

60 The heat of our fires has been derived from the solar fire. We cannot lift a weight in the hand without the combustion of a certain amount of food; 61 we cannot think a thought without a similar demand; and the force that goes in one way is unavailable in any other way. 62 While we are expending ourselves largely in any single function-- in muscular exercise, in digestion, in thought and feeling, the remaining functions must continue for the time in comparative abeyance. 63 Now, the maintenance of a high strain of elated feeling, unquestionably costs a great deal to the forces of the system. All the facts confirm this high estimate. 64 An unusually copious supply of arterial blood to the brain is an indispensable requisite, even although other organs should be partially starved, and consequently be left in a weak condition, or else deteriorate before their time.

65 To support the excessive demand of power for one object, less must be exacted from other functions. 66 Hard bodily labour and severe mental application sap the very foundations of buoyancy; they may not entail much positive suffering, but they are scarcely compatible with exuberant spirits. 67 There may be exceptional individuals whose total of power is a very large figure, who can bear more work, endure more privation, and yet display more buoyancy, without shortened life, than the average human being. 68 Hardly any person can attain commanding greatness without being constituted larger than own fellows in the sum of human vitality. 69 But until this is proved to be the fact in any given instance, we are safe in presuming that extraordinary endowment in one thing implies deficiency in other things. 70 More especially must we conclude, provisionally at least, that a buoyant, hopeful, elated temperament lacks some other virtues, aptitudes, or powers, such as are seen flourishing in the people whose temperament is sombre, inclining to despondency. 71 Most commonly the contradictory demand is reconciled by the proverbial "short life and merry".

72 Adverting now to the object that Helps had so earnestly at heart--

namely, to rouse and rescue the English population from their comparative dulness to a more lively and cheerful flow of existenc-- 73 let us reflect how, upon the foregoing principles, this is to be done. Not certainly by an eloquent appeal to the nation to get up and be amused. The process will turn out to be a more circuitous one.

74 The mental conformation of the English people, which we may admit to be less lively and less easily amused than the temperament of Irishmen, Frenchmen, Spaniards, Italians, or even the German branch of our own Teutonic race, 75 is what it is from natural causes, whether remote descent, or that coupled with the operation of climate and other local peculiarities. 76 How long would it take, and what would be the way to establish in us a second nature on the point of cheerfulness?

77 Again, with the national temperament such as it is, there may be great individual differences; 78 and it may be possible by force of circumstances, to improve the hilarity and the buoyancy of any given person. 79 Many of our country people are as joyous themselves, and as much the cause of joy in others, as the most light-hearted Irishman, or the gayest Frenchman or Italian. 80 How shall we increase the number of such, so as to make them the rule rather than the exception?

SOLE MEANS OF ATTAINING CHEERFULLNESS

81 The only answer not at variance with the laws of the human constitution is-- Increase the supports and diminish the burdens of life. 82 For example, if by any means you can raise the standard of health and longevity, you will at once effect a stride in the direction sought. 83 But what an undertaking is this! It is not merely setting up what we call sanitary arrangements, to which, in our crowded populations, there must soon be a limit reached-- 84 for how can you secure to the mass of people even the one condition of sufficient breathing-space?,-- 85 it is that health cannot be attained, in

any high general standard, without worldly means far above the average at the disposal of the existing population; 86 while the most abundant resources are often neutralised by ineradicable hereditary taint. 87 To which it is to be added, that humankind can hardly as yet be said to be in earnest in the matter of health.

88 Farther: it is especially necessary to cheerfulness, that a human should not be overworked, as many of us are, whether from choice or from necessity. 89 Much, I believe, turns upon this circumstance. Severe toil consumes the forces of the constitution, without leaving the remainder requisite for hilarity of tone. 90 The Irishman fed upon three meals of potatoes a day, the lazy Highlander, the Lazaroni of Naples living upon sixpence a week, are very poorly supported; 91 but then their vitality is so little drawn upon by work, that they may exceed in buoyancy of spirits the well-fed but hard-worked labourer. 92 We, the English people, would not change places with them, notwithstanding: our ideal is industry with abundance; but then our industry sobers our temperament, and inclines us to the dulness that Helps regrets. 93 Possibly, we may one day hit a happier mean; but to the human mind extremes have generally been found easiest.

94 Once more: the light-hearted races trouble themselves little about their political constitution, about despotism or liberty; 95 they enjoy the passing moments of a despot's smiles, and if you turns round and crushes them, they quietly submit. 96 We live in dread of tyranny. Our liberty is a serious object; it weighs upon our minds. 97 Now any weight upon the mind is so much taken from our happiness; hilarity may attend on poverty, but not so well on a serious, forecasting disposition. 98 Our regard to the future makes us both personally industrious and politically anxious; a temper not to be amused with the relaxations of the Parisian in own café on the boulevards, or with the Sunday merry-go-round of the light-hearted Dane. 99 Our very pleasures have still a sadness in them.

100 Then, again, what are to be our amusements? By what recreative stimulants shall we irradiate the gloom of our idle hours and vacation periods? 101 Doubtless there have been many amusements invented by the benefactors of our species-- society, games, music, public entertainments, books; 102 and in a well-chosen round of these, many contrive to pass their time in a tolerable flow of satisfaction. 103 But they all cost something; they all cost money, either directly, to procure them, or indirectly, to be educated for them. 104 There are few very cheap pleasures. Books are not so difficult to obtain, but the enjoying of them in any high degree implies an amount of cultivation that cannot be had cheaply.

105 Moreover, look at the difficulties that beset the pursuit of amusements. How fatiguing are they very often! How hard to distribute the time and the strength between them and our work or our duties! 106 It needs some art to steer one's way in the midst of variety of pleasures. 107 Hence there will always be, in a cautious-minded people, a disposition to remain satisfied with few and safe delights; 108 to assume a sobriety of aims that Helps might call dullness, but that many of us call the middle path.

FALLACY OF PRESCRIBING TASTES

109 A second error against the limits of the human powers is the prescribing to persons indiscriminately, certain tastes, pursuits, and subjects of interest, 110 on the ground that what is a spring of enjoyment to one or a few may be taken up, as a matter of course, by others with the same relish. 111 It is, indeed, a part of happiness to have some taste, occupation, or pursuit, adequate to charm and engross us-- a ruling passion, a favourite study. 112 Accordingly, the victims of dullness and ‘ennui’ are often advised to betake themselves to something of this potent character. 113 Kingsley, in his little book on the "Wonders of the Shore," endeavoured to convert humankind at large into marine naturalists; 114 and, some time ago, there appeared in the

newspapers a letter from Carlyle, regretting that he himself had not been indoctrinated into the zoology of our waysides. 115 I have heard a man out of health, hypochondriac, and idle, recommended to begin botany, geology, or chemistry, as a diversion of his misery. 116 The idea is plausible and superficial. An overpowering taste for any subject--botany, zoology, antiquities, music-- is properly affirmed to be born with a human.

117 The forces of the brain must from the first incline largely to that one species of impressions, to which must be added years of engrossing pursuit. 118 We may gaze with envy at the fervour of a botanist over own dried plants, and may wish to take up so fascinating a pursuit: 119 we may just as easily wish to be Archimedes when he leaped out of the bath; a person cannot re-cast own brain nor re-live own life. 120 A taste of a high order, founded on natural endowment, formed by education, and strengthened by active devotion, is also paid for by the atrophy of other tastes, pursuits, and powers. 121 Carlyle might have contracted an interest in frogs, and spiders, and bees, and the other denizens of the wayside, 122 but it would have been with the surrender of some other interest, the diversion of his genius out of its present channels.

123 The strong emotions of the mind are not to be turned off and on, to this subject and to that. 124 If you begin early with a human being, you may impress a particular direction upon the feelings, you may even cross a natural tendency, and work up a taste on a small basis of predisposition. 125 Place any youth in the midst of artists, and you may induce a taste for art that shall at length be decided and strong. 126 But if you were to take the same person in middle life and immured in a labouratory, that one might become an enthusiastic chemist, the limits of human nature would probably forbid your success.

127 Such very strong tastes as impart a high and perennial zest to one's life are merely the special direction of a natural exuberance of feeling or emotion. 128 A spare and thin emotional temperament

will undoubtedly have preferences, likings and dislikings, but it can never supply the material for fervour or enthusiasm in anything.

129 The early determining of natural tastes is a subject of high practical interest. We shall only remark at present that a varied and broad groundwork of early education is the best known device for this end.

RELATION OF FEELINGS TO IMAGINATION

130 A third error, deserving of brief comment, is a singular inversion of the relationship of the Feelings to the Imagination. 131 It is frequently affirmed, both in criticism and in philosophy, that the Feelings depend upon, or have their basis in, the Imagination.

132 An able and polished writer, discussing the character of Edmund Burke, remarks: "The passions of Burke were strong; this is attributable in great measure to the intensity of the imaginative faculty". 133 Again, Dugald Stewart, observing upon the influence of the Imagination on Happiness, says: "All that part of our happiness or misery which arises from our hopes or our fears derives its existence entirely from the power of imagination". 134 He even goes the length of affirming that "cowardice is entirely a disease of the imagination". 135 Another writer accounts for the intensity of the amatory sentiments in Robert Burns by the strength of his imagination.

IMAGINATION GROUNDED IN FEELING

136 Now, I venture to affirm that this view very nearly reverses the fact. The Imagination is determined by the Feelings, and not the Feelings by the Imagination. 137 Intensity of feeling, emotion, or passion, is the earlier fact: the intellect swayed and controlled by feeling, shaping forms to correspond with an existing emotional tone, is Imagination. 138 It was not the imaginative faculty that gave Wordsworth, Byron, Shelley, and the poets generally, their great enjoyment of Nature; 139 but the love of Nature, pre-existing,

turned the attention and the thoughts upon Nature, filling the mind as a consequence with the impressions, images, recollections of Nature; out of which grew the poetic imaginings.

140 Imagination is a compound of intellectual power and feeling. 141 The intellectual power may be great, but if it is not accompanied with feeling, it will not minister to feeling; or it will minister to many feelings by turns, and to none in particular. 142 As far as the intellectual power of a poet goes, few people have excelled Bacon. 143 He had a mind stored with imagery, able to produce various and vivid illustrations of whatever thought came before him; 144 but these illustrations touched no deep feeling; they were fresh, original, racy, fanciful, picturesque, a play of the head that never touched the heart. 145 The man was by nature cold; he had not the emotional depth or compass of an average Englishman. 146 Perhaps his strongest feeling of an enlarged or generous description was for human progress, but it did not rise to passion; there was no fervour, no fury in it.

147 Compare him with Shelley on the same subject, and you will see the difference between meagreness and intensity of feeling. 148 What intellect can be, without strong feeling, we have in Bacon; what intellect is, with strong feeling, we have in Shelley. 149 The feeling gives the tone to the thoughts; sets the intellect at work to find language having its own intensity, to pile up lofty and impressive circumstances; 150 and then we have the poet, the orator, the thoughts that breathe, and the words that burn. 151 Bacon wrote on many impressive themes-- on Truth, on Love, on Religion, on Death, and on the Virtues in detail; he was always original, illustrative, fanciful; 152 if intellectual means and resources could make a person feel in these things, he would have felt deeply; yet he never did. 153 The material of feeling is not contained in the intellect; it has a seat and a source apart. 154 There was nothing in mere intellectual gifts to make Byron a misanthrope: 155 but, given that state of the feelings, the intellect would be detained and engrossed by it; would minister to,

expand, and illustrate it; and intellect so employed is Imagination.

156 Burke had indisputably a powerful imagination. He had both elements:-- the intellectual power, or the richly stored and highly productive mind; and the emotional power, or the strength of passion that gives the lead to intellect. 157 His intellectual strength was often put forth in the Baconian manner of illustration, in light and sportive fancies. 158 There were many occasions where his feelings were not much roused. 159 He had topics to urge, views to express, and he poured out arguments, and enlivened them with illustrations. 160 He was, on those occasions, an able expounder, and no more. 161 But when his passions were stirred to the depths by the French Revolution, his intellectual power, taking a new flight, supplied him with figures of extraordinary intensity; 162 it was no longer the play of a cool man, but the thunders of an aroused man; we have then "the hoofs of the swinish multitude,"-- "the ten thousand swords leaping from their scabbards". 163 Such feelings were not produced by the speaker's imagination: they were produced by themselves; 164 they had their independent source in the region of feeling: coupled with adequate powers of intellect, they burst out into strong imagery.

165 The Orientals, as a rule, are distinguished for imaginative flights. This is apparent in their religion, their morality, their poetry, and their science. 166 The explanation is to be sought in the strength of their feelings, coupled with a certain intellectual force. The same intellect, without the feelings, would have issued differently. The Chinese are the exception. 167 They want the feelings, and they want the imagination. They are below Europeans in this respect. 168 When we bring before them our own imaginative themes, our own cast of religion, accommodated as it is to our own peculiar temperament, we fail in the desired effect. 169 Our august mysteries are responded to, not with reverential regard, but with, cold analysis.

170 The Celt and the Saxon are often contrasted on the point of imagination; the prior fact is the comparative endowment for emotion.

HOW HAPPINESS SHOULD BE AIMED AT

171 There is a fallacious mode of presenting the attainment of happiness; namely, that happiness is best secured by not being aimed at. We should be aiming always at something else. 172 When examined closely, the doctrine resolves itself into a kind of paradox. All sorts of puzzles come up when we attempt to follow it to its consequences.

173 We might ask, first, whether there is any other object of pursuit in the same predicament-- wealth, health, knowledge, fame, power. 174 These are, every one, a means or instrument of happiness, if not happiness itself. Must we, then, in the case of each, avoid aiming straight at the goal? Must we look askance in some other direction?

175 Next, in the case of happiness proper, are we to aim at nothing at all, to drift at random; or may we aim at a definite object, provided it is not happiness; or, lastly, is there one side aim in particular that we must take? 176 The answer here would probably be-- Aim at duty in general, and at the good of others in particular. 177 These ends are not the same as happiness, yet by keeping them steadily in the view, and not thinking of self at all, we shall eventually realise our greatest happiness.

178 Without, at present, raising any question as to the fact alleged, we must again remark that the prescription seems to contradict itself. 179 Moralists of the austere type will never allow us to pursue happiness at all; we must never mention the thing to ourselves: duty or virtue is the one single aim and end of being. 180 Such teachers may be right or they may be wrong, but they do not contradict themselves. 181 When, however, we are told that by aiming at virtue, we are on the best possible road to happiness, this is but another way of letting us into the secret of happiness, of putting us on the right, instead of on the wrong track to attain it. 182 Our

teacher assumes that we are in search of happiness, and they tells us how we are to proceed; not by keeping it straight in the view, but by keeping virtue straight in the view. 183 Instead of pointing us to the vulgar happiness-seeker who would take the goal in a line, they corrects the course, and shows us the deviation that is necessary in order to arrive at it; 184 like the sailor making allowance for the deviation of the magnetic pole, in steering. 185 Happiness is not gained by a point-blank aim; we must take a boomerang flight in some other line, and come back upon the target by an oblique or reflected movement. 186 It is the idea of Young on the Love of Praise (Satire I., 5.)--

> The love of Praise howe'er
> concealed by art,
> Reigns more or less and glows in
> every heart,
> The proud to gain it, toils on toils
> endure,
> The modest shun it but to make it
> sure.

187 Under this corrected method, we are happiness seekers all the same; only our aims are better directed, and our fruition more assured.

188 These remarks are intended to show that the doctrine of making people aim at virtue, in order to happiness, has no further effect than to teach us to include the interests of others with our own; 189 by showing that our own interests do not thereby suffer, but the contrary. 190 The doctrine does not substitute a virtuous motive for a selfish one; it is a refined artifice for squaring the two. 191 The world is no doubt a gainer by the change of view, although the individual is not made really more meritorious.

192 We must next consider whether, in fact, the oblique aim at happiness is really the most effectual. 193 A few words, first, as to the original source of the doctrine of a devious course. 194 Bishop Butler is renowned for his distinction between Self-Love and Appetite; he contends that in Appetite the object of pursuit is not the pleasure of eating, but the food: 195 consequently, eating is not properly a self-seeking act, it is an indifferent or disinterested act, to which there is an incidental

accompaniment of pleasure. 196 We should, under the stimulus of Hunger, seek the food, whether it gave us pleasure or not.

197 Now, any truth that there is in Butler's view amounts to this:-- In our Appetites we are not thinking every instant of subduing pain and attaining pleasure; we are ultimately moved by these feelings; 198 but, having once seen that the medium of their gratification is a certain material object (food), we direct our whole aim to procuring that. 199 The hungry wolf ceases to think of own pains of hunger when it is in sight of a sheep; 200 but for these pains it would have paid no heed to the sheep; yet when the sheep has to be caught, the hunger is submerged for the time; 201 the only relevant course, even on its account, is to give the whole mind and body to the chase of the sheep. 202 Butler calls this indifferent or disinterested pursuit; and as much as says, that the wolf is not self-seeking, but sheep-seeking, in its chase. 203 Now, it is quite true that if the wolf could give no place in its mind for anything but its hungry pains, it would be in a bad way. 204 It is wiser than that; it knows the remedy; it is prepared to dismiss the pains from its thoughts, in favour of a concentrated attention upon the distant flock. 205 This proves nothing as to its unselfishness; nor does it prove that Appetite is a different thing from self-seeking or self-love.

APPETITE DECLARED UNSELFISH

206 There may be disinterested motives in our constitution; but Appetite is not in any sense one of these. 207 We may have instincts answering to the traditional phrase used in defining instinct, "a blind propensity" to act, without aiming at anything in particular, and without any expectation of pleasure or benefit. 208 Such instincts would conform to Butler's notion of appetite: they would be entirely out of the course of self-love or self-seeking of any sort. 209 Whether the nest-building activity of birds, and the constructiveness of ants, bees, and beavers, comply with this

condition, I do not undertake to say. 210 There is one process better known to ourselves, not exactly an instinct, but probably a mixture of instinct and acquirement-- I mean the process of Imitation-- which works very much upon this model. 211 Although coming under the control of the Will, yet in its own proper character it operates blindly, or without purpose; neither courting pleasure, nor chasing pain. 212 In like manner, Sympathy, in its most characteristic form, proceeds without any distinct aim of pleasure to ourselves.

213 Nothing of this can be affirmed of the Appetites. In them, Nature places us, as Bentham says, under the government of two sovereign masters, pain and pleasure. 214 An appetite would cease to move us, if its painful and pleasurable accompaniments were done away with. 215 It matters not that we remit our attention, at times, to the pain or the pleasure; these are always in the background; and the strength of the appetite is their strength.

216 So far as concerns Butler's example of the Appetites, there is no case for the view that to obtain happiness we must avoid aiming at it directly. 217 If we do not aim at the pleasure in its own subjective character, we aim at the thing that immediately brings the pleasure; which is, for all practical purposes, to aim at the pleasure.

218 The prescription to look away from the final end, Happiness, in order to secure that end, may be tested on the example of one of our intermediate pursuits, as Health. 219 It is not a good thing to be always dwelling on the state of our health: by doing so, we get into a morbid condition of self-consciousness, which is in itself pernicious. 220 It does not follow that we are to live at random, without ever giving a thought to our health. There is a plain middle course. 221 Guided by our own experience, and by the experience of those that have gone before us, we arrange our plan of life so as to preserve health; and our actions consist in adhering to that plan in the detail. 222 So long as our scheme answers expectation, we think of nothing but of putting it in force, as occasion arises; we do not dwell upon our states of good

health at all. 223 It is some interruption that makes us self-conscious; and then it is that we have to exercise ourselves about a remedial course. 224 This, when found, is likewise objectively pursued; our only subjectiveness lies in being aware of gradual recovery; and we are glad to get back to the state of paying no attention to the workings of our viscera. 225 We do not, therefore, remit our pursuit; only, it is enough to observe the routine of outward actions, whose sole motive is to keep us in health.

226 The pursuit of the still wider end, Happiness, has much in common with the narrower pursuit. 227 When we have discovered what things promote, and what things impede our happiness, we transfer our attention to these, as the most direct mode of compassing the end. 228 If we are satisfied that working for other people brings us happiness, we work accordingly; this is no side aim, it is as direct as any aim can be. 229 It may involve immediate sacrifice, but that does not alter the case; we can get no considerable happiness from any source without temporary sacrifice.

HAPPINESS AND VIRTUE DISTINCT AIMS

230 If it be said that the best mode of attaining happiness is to put ourselves entirely out of account, and to work for others exclusively, this, as already noted, is a self-contradiction. 231 It is to tell people not to think of their own happiness, and yet to know that they are securing that in the most effectual way. It is also very questionable, indeed absolutely erroneous, in fact. 232 The most apparent way to secure happiness is to ply all the known means of happiness, just as far as, and no farther than, they are discovered to produce the effect. 233 We must keep a check upon the methods that we employ, and abandon those that do not answer. 234 So long as we find happiness in serving others, so long we continue in that course. 235 And it is a melancholy fact that Pope's bold assertion-- "Virtue alone is happiness below," --cannot be

upheld against the stern realities of life. 236 Life needs to be made up of two aims-- the one, Happiness, the other Virtue, each on its own account. 237 There is a certain mutual connection of the two, but all attempts at making out their identity are failures.

238 It is of very great importance to teach people the bearings of virtue on happiness, so far as these are known. 239 There will, however, always remain a portion of duty that detracts from happiness, and must be done as duty, nevertheless. 240 People are entitled to pursue happiness as directly as ever they please; only, they must couple with the pursuit their round of duties to others; in which they may or may not reap a share of the coveted good for self.

241 Let us, next, consider some of the difficulties and mistakes attaching to the WILL. Here there are the questions of world-renown, questions known even in Pandemonium-- Free-will, Responsibility, Moral Ability, and Inability. 242 It is now suspected, on good grounds, that, on these questions, we have somehow got into a wrong groove-- that we are lost in a maze of our own constructing.

A STRONG WILL
THE GIFT OF NATURE

243 We shall first notice a misconception akin to some of the foregoing mistakes respecting the feelings. 244 In addressing people with a view to spur their activity, there is usually a too low estimate of what is implied in great and energetic efforts of will. 245 Here, exactly as in the cheerful temperament, we find a certain constitutional endowment, a certain natural force of character, having its physical supports of brain, muscle, and other tissue; 246 and neither persuasion, nor even education, can go very far to alter that character. 247 If there be anything at all in the observations of phrenology, it is the connection of energetic determination with size of brain. 248 Lay your hand first on the head of an energetic person, and then on the head of a feeble person, and you will find a difference that is not to be explained away. 249 Now it passes all the powers of persuasion and

education combined to make up for a great cranial inequality. 250 Something always comes of assiduous discipline; but to set up a King Alfred, or a Luther, as a model to be imitated by an ordinary person, on the points of energy, perseverance, endurance, courage, is to pass the bounds of the human constitution. 251 Persistent energy of a high order, like the temperament for happiness, costs a great deal to the human system. 252 A large share of the total forces of the constitution go to support it; and the diversion of power often leaves great defects in other parts of the character, as for example, a low order of the sensibilities, and a narrow range of sympathies. 253 The people of extraordinary vigour and activity-- our Roman emperors and conquering heroes-- are often brutal and coarse. 254 Nature does not supply power profusely on all sides; and delicate sympathies, of themselves, use up a very large fraction of the forces of the organisation. 255 Even intellectually estimated, the power of sympathising with many various minds and conditions would occupy as much room in the brain as a language, or an accomplishment. 256 A person both energetic and sympathetic-- a Pericles, a King Alfred, an Oliver Cromwell-- is one of Nature's giants, several people in one.

257 There is no more notable phase of our active nature than Courage. 258 Great energy generally implies great courage, and courage-- at least in nine-tenths of its amount-- comes by Nature. 259 To exhort any one to be courageous is waste of words. We may animate, for the time, a naturally timid person, by explaining away the signs of danger, and by assuming a confident attitude ourselves; 260 but the absolute force of courage is what neither we nor the person can add to. 261 A long and careful education might effect a slight increase in this, as in other aspects of energy of character: 262 we can hardly say how much, because it is a matter that is scarcely ever subjected to the trial; the very conditions of the experiment have not been thought of.

263 The moral qualities expressed by Prudence, Forethought, Circumspection, are talked of with

a like insufficient estimate of what they cost. 264 Great are the rewards of prudence, but great also is the expenditure of the prudent person. 265 To retain an abiding sense of all the possible evils, risks and contingencies of an ordinary person's position-- professional, family, and personal-- is to go about under a constant burden; 266 the difference between a thorough-going and an easy-going circumspection is a large additional demand upon the forces of the brain. 267 The being on the alert to duck the head at every bullet is a charge to the vital powers; so much so, that there comes a point when it is better to run risks than to pile up costly precautions and bear worrying anxieties.

268 Lastly, the attribute of our active nature called Belief, Confidence, Conviction, is subject to the same line of remark. 269 This great quality-- the opposite of distrust and timidity, the ally of courage, the adjunct of a buoyant temperament-- is not fed upon airy nothings. 270 It is, indeed, a true mental quality, an offshoot of our mental nature; yet, although not material, it is based upon certain forces of the physical constitution; it grows when these grow, and is nourished when they are nourished. 271 People possessed of great confidence have it as a gift all through life, like a broad chest or a good digestion. 272 Preaching and education have their fractional efficacy, and deserve to be plied, provided the operator is aware of Nature's impassable barriers, and does not suppose that you are working by charm. 273 It is said of Hannibal that he dissolved obstructions in the Alps by vinegar; in the moral world, barriers are not to be removed either by acetic acid or by honey.

PREJUDICES DUE TO PERSONAL DIGNITY

274 The question of Free-will might be a text for discoursing on some of the most inveterate erroneous tendencies of the mind. 275 For one thing, it gives occasion to remark on the influence exerted over our opinions by the feeling of Personal Dignity. 276 Of sources of bias, prejudices, "Idola,"

"fallacies a-priori" this may be allowed precedence. 277 For example, the maxim has been enunciated by some philosophers, that, of two differing opinions, preference is to be given-- not to what is true, but-- to what ennobles and dignifies human nature. 278 One of the objections seriously entertained against Darwin's theory is that it humbles our ancestral pride. 279 So, to ascribe to our mental powers a material foundation is held to be degrading to our nobler part. 280 Again, a philosopher of our own day-- Sir W. Hamilton-- has placed on the title-page of his principal work this piece of rhetoric: "On earth, there is nothing great but human; in human, there is nothing great but mind". 281 Now one would suppose that there are on earth many things besides human deserving the appellation of "great"; 282 and that the mechanism of the body is, in any view, quite as remarkable a piece of work as the mechanism of the mind. 283 There was one step more that Hamilton, as an Aristotelian, should have made: "In mind, there is nothing great but intellect". 284 Doubtless, we ought not to dissect an epigram; but epigrams brought into a perverting contact with science are not harmless. 285 Such gross pandering to human vanity must be held as disfiguring a work on philosophy.

286 The sentiment of dignity has much to answer for in the doctrine of Free-will. 287 In Aristotle, the question had not assumed its modern perplexity; but the vicious element of factitious personal importance had already peeped out, 288 it being one of the few points wherein the bias of the feelings operated decidedly in his well-balanced mind. 289 In maintaining the doctrine that vice is voluntary, he argues, that if virtue is voluntary, vice-- its opposite-- must also be voluntary; 290 now to assert virtue not to be voluntary would be to cast an indignity upon it. 291 This is the earliest association of the feeling of personal dignity with the exercise of the human will.

FALSE PRIDE IN CONNECTION WITH FREE-WILL

292 The Stoics are commonly said to have started the free-will difficulty. This needs an explanation. 293 A leading tenet of theirs was the distinction between things in our power and things not in our power; and they greatly overstrained the limits of what is in our power. 294 Looking at the sentiment about death, where the idea is everything, and at many of our desires and aversions, also purely sentimental, that is, made and unmade by our education-- as, for example, pride of birth--, 295 they considered that pains in general, even physical pains and grief for the loss of friends, could be got over by a mental discipline, by intellectually holding them not to be pains. 296 They extolled and magnified the power of the will that could command such a transcendent discipline, and infused an emotion of pride into the consciousness of this greatness of will. 297 In subsequent ages, poets, moralists, and theologians followed up the theme; and the appeal to the pride of will may be said to be a standing engine of moral suasion. 298 This originating of a point of honour or dignity in connection with our Will has been the main lure in bringing us into the jungle of Free-will and Necessity.

299 It is in the Alexandrian school that we find the next move in the question. In Philo Judaeus, the good person is spoken of as free, the wicked person as a slave. 300 Except as the medium of a compliment to virtue, the word "freedom" is not very apposite, seeing that, to the highest goodness, there attaches submission or restraint, rather than liberty.

301 The early Christian Fathers-- notably Augustine-- advanced the question to the Theological stage, by connecting it with the great doctrines of Original Sin and Predestination; 302 in which stage it shared all the speculative difficulties attaching to these doctrines. 303 The Theological world, however, has always been divided between Free-will and Necessity; and probably the weightiest names are to be found among the Necessitarians. 304 No person ever brought greater

acumen into theological controversy than did Jonathan Edwards; and he took the side of Necessity.

305 Latterly, however, since the question has become one of pure metaphysics, Free-will has been the favourite dogma, as being most consonant to the dignity of human, which appears to be its chief recommendation, and its only argument. 306 The weight of reasoning is, I believe, in favour of necessity; but the word carries with it a seeming affront, and hardly any amount of argument will reconcile people to indignity.

307 Another weakness of the human mind receives illustration from the free-will controversy, and deserves to be noticed, as helping to account for the prolonged existence of the dispute: 308 I mean the disposition to regard any departure from the accustomed rendering of a fact as denying the fact itself. 309 The rose under another name is not merely less sweet, it is not a rose at all. Some of the greatest questions have suffered by this weakness.

ANALYSIS DOES NOT DESTROY THE FACT

310 The physical theory of matter that resolves it into points of force will seem to many as doing away with matter no less effectually than the Berkeleyan Idealism. 311 A universe of inane mathematical points, attracting and repelling each other, must appear to the ordinary mind a sorry substitute for the firm-set earth, and the majestically-fretted vault of heaven, with its planets, stars, and galaxies. 312 It takes a special education to reconcile any one to this theory. 313 Even if it were everything that a scientific hypothesis should be, the previously established modes of speech would be a permanent obstruction to its being received as the popular doctrine.

314 But the best illustrations occur in the Ethical and Metaphysical departments. For example, some ethical theorists endeavour to show that Conscience is not a primitive and distinct power of the mind, 315 like the sense of colour, or the feeling of resistance, but a growth and a compound, being

made up of various primitive impulses, together with a process of education. 316 Again and again has this view been represented as denying conscience altogether. Exactly parallel has been the handling of the sentiment of Benevolence. 317 Some have attempted to resolve it into simpler elements of the mind, and have been attacked as denying the existence of the sentiment. 318 Hobbes, in particular, has been subjected to this treatment. Because he held pity to be a form of self-love, his opponents charged him with declaring that there is no such thing as pity or sympathy in the human constitution.

319 A more notable example is the doctrine of the alliance of Mind with Matter. It is impossible that any mode of viewing this alliance can erase the distinction between the two modes of existence-- the material and the mental; 320 between extended inert bodies, on the one hand, and pleasures and pains, thoughts and volitions, on the other. 321 Yet, after the world has been made familiar with the Cartesian doctrine of two distinct substances-- the one for the inherence of material facts, and the other for mental facts-- 322 any thinker maintaining the separate mental substance to be unproved, and unnecessary, is denounced as trying to blot out our mental existence, and to resolve us into watches, steam-engines, or speaking and calculating machines. 323 The upholder of the single substance has to spend the self in protestations that one is not denying the existence of the fact, or the phenomena called mind, but is merely challenging an arbitrary and unfounded hypothesis for representing that fact.

PERCEPTION OF A MATERIAL WORLD

324 The still greater controversy-- distinct from the foregoing, although often confounded with it-- relating to the Perception of a Material World, is the crowning instance of the weakness we are considering. 325 Berkeley has been unceasingly stigmatised as holding that there is no material world, merely because he exposed a self-contradiction in the mode of

viewing it, 326 common to the vulgar and to philosophers, and suggested a mode of escaping the contradiction by an altered rendering of the facts. The case is very peculiar. 327 The received and self-contradictory view is exceedingly simple and intelligible in its statement; it is well adapted, not merely for all the commoner purposes of life, but even for most scientific purposes. 328 The supposition of an independent material world, and an independent mental world, created apart, and coming into mutual contact-- 329 the one the objects perceived, and the other the mind perceiving-- expresses or over-expresses the division of the sciences into sciences of matter and sciences of mind; 330 and the highest laws of the material world at least are in no respect falsified by it.

331 On the other hand, any attempt to state the facts of the outer world on Berkeley's plan, or on any plan that avoids the self-contradiction, is most cumbrous and unmanageable. 332 A smaller, but exactly parallel instance of the situation is familiar to us. 333 The daily circuit of the sun around the earth, supposed to be fixed, so exactly answers all the common uses that, in spite of its being false, we adhere to it in the language of every-day life. 334 It is a convenient misrepresentation, and deceives nobody. And such will, in all likelihood, be the usage regarding the external world, after the contradiction is admitted, and rectified by a metaphysical circumlocution. 335 Speculators are still only trying their hand at an unobjectionable circumlocution; but we may almost be sure that nothing will ever supersede, for practical uses, the notion of the distinct worlds of Mind and Matter. 336 If, after the Copernican demonstration of the true position of the sun, we still find it requisite to keep up the fiction of his daily course; 337 much more, after the final accomplishment of the Berkeleyan revolution-- to my mind inevitable--, shall we retain the fiction of an independent external world: 338 only, we shall then know how to fall back upon some mode of stating the case, without incurring the contradiction.

339 To return to the Will. The fact that we have to save, and to represent in adequate language, is this:-- A voluntary action is a sequence distinct and ‘sui generis’; 340 a human being avoiding the cold, searching for food, and clinging to other beings, is not to be confounded with a pure material sequence, as the fall of rain, or the explosion of gunpowder. 341 The phenomena, in both kinds, are phenomena of sequence, and of regular or uniform sequence; but the things that make up the sequence are widely different: 342 in the one, a feeling of the mind, or a concurrence of feelings, is followed by a conscious muscular exertion; in the other, both steps are made up of purely material circumstances. 343 It is the difference between a mental or psychological, and a material or physical sequence-- in short, the difference between mind and matter; the greatest contrast within the whole compass of Nature, within the universe of being.

344 Now language must be found to give ample explicitness to this diametrical antithesis; 345 still, I am satisfied that rarely in the usages of human speech has a more unfortunate choice been made than to employ, in the present instance, the antithetic couple-- Freedom and Necessity. 346 It misses the real point, and introduces meanings alien to the case. 347 It converts the glory of the human character into a reproach-- although its leading motive throughout has been to pay us a compliment. 348 The constancy of human's emotional nature-- but for which our life would be a chaos, an impossibility-- 349 has to be explained away, for no other reason than that, at one time, a blundering epithet was applied to designate the mental sequences. 350 Great is the difference between Mind and Matter; but the terms Freedom and Necessity represent the point of agreement as the point of difference; 351 and this being made familiar, through iteration, as the mode of expressing the contrast, the rectification is supposed to unsettle everything, and to obliterate the wide distinction of the two natures.

SEIZING A QUESTION BY THE WRONG END

352 What is called Moral Ability and Inability is another artificial perplexity in regard to the will, and might also be the text for a sermon on prevailing errors. 353 More especially, it exemplifies what may be termed seizing a question by the wrong end.

354 The votary, we shall say, of alcoholic liquor is found fault with, and makes the excuse, you cannot help it-- you cannot resist the temptation. So far, the language may pass. 355 But what shall we say to the not uncommon reply,-- You could help it if you would. 356 Surely there is some mystification here; it is not one of those plain statements that we desire in practical affairs. 357 Whether we are dealing with matter or with mind, we ought to point out some clear and practicable method of attaining an end in view. 358 To get a good crop, we till and enrich the soil; to make the youths knowing in mathematics, we send them to good masters, and stimulate their attention by combined reward and punishment.

359 There are also intelligible courses of reforming the vicious: withdraw them from temptation till their habits are re-modelled; 360 entice them to other courses, by presenting objects of superior attraction; or, at lowest, keep the fact of punishment before their eyes. 361 By these methods many are kept from vices, and not a few reclaimed after having fallen. 362 But to say, "You can be virtuous if you will," is either unmeaning, or it disguises a real meaning. 363 If it have any force at all-- and it would not be used unless, some efficacy had been found attaching to it,-- the force must be in the indirect circumstances or accompaniments. 364 What, then, is the meaning that is so unhappily expressed? In the first place, it is a vehicle for conveying the strong wish and determination of the speaker; 365 it is a clumsy substitute for-- "I do wish you would amend your conduct"; an expression containing a real efficacy, greater or less according to the estimate formed of the speaker by the person spoken to. 366 In the next place, it

presents to the mind of the delinquent the ideal of improvement, which might also be done in unexceptionable phrase; 367 as one might say-- "Reflect upon your own state, and compare yourself with the correct and virtuous liver". Then, there is a touch of the stoical dignity and pride of will. 368 Lastly, there may be a hint or suggestion to the mind of good and evil consequences, which is the most powerful motive of all. 369 In giving rise to these various considerations, even the objectionable expression may have a genuine efficacy; 370 but that does not justify the form itself, which by no interpretation can be construed into sense or intelligibility.

MEANING OF MORAL INABILITY

371 Moral Inability means that ordinary motives are insufficient, but not all motives. 372 The confirmed drunkard or thief has got into the stage of moral inability; the common motives that keep humankind sober and honest have failed. 373 Yet there are motives that would succeed, if we could command them. 374 People may be sometimes cured of intemperance when the constitution is so susceptible that pain follows at once on indulgence.

375 And so long as pleasure and pain, in fact and in prospect, operate upon the will, so long as the individual is in a state wherein motives operate, there may be moral weakness, but there is nothing more. 376 In such cases, punishment may be properly employed as a corrective, and is likely to answer its end. 377 This is the state termed accountability, or, with more correctness, PUNISHABILITY, for being accountable is merely an incident bound up with liability to punishment. 378 Moral weakness is a matter of a degree, and in its lowest grades shades into insanity, the state wherein motives have lost their usual power-- when pleasure and pain cease to be apprehended by the mind in their proper character. 379 At this point, punishment is unavailing; the moral inability has passed into something like physical inability;

the loss of self-control is as complete as if the muscles were paralysed.

380 In the plea of insanity, entered on behalf of any one charged with crime, the business of the jury is to ascertain whether the accused is under the operation of the usual motives-- whether pain in prospect has a deterring effect on the conduct. 381 If a person is as ready to jump out of the window as to walk downstairs, of course you are not a moral agent; 382 but so long as you observes, of your own accord, the usual precautions against harm to yourself, you are to be punished for your misdeeds.

383 These various questions respecting the Will, if stripped of unsuitable phraseology, are not very difficult questions. 384 They are about as easy to comprehend as the air-pump, the law of refraction of light, or the atomic theory of chemistry. 385 Distort them by inapposite metaphors, view them in perplexing attitudes, and you may make them more abstruse than the hardest proposition of the "Principia". 386 What is far worse, by involving a simple fact in inextricable contradictions, they have led people gravely to recognise self-contradiction as the natural and the proper condition of a certain class of questions. 387 Consistency is very well so far, and for the humbler matters of every-day life, but there is a higher and a sacred region where it does not hold; 388 where the principles are to be received all the more readily that they land us in contradictions. 389 In ordinary matters, inconsistency is the test of falsehood; in transcendental subjects, it is accounted the badge of truth.

ERRORS OF SUPPRESSED CORRELATIVES

Alexander Bain

13 By Relativity is here meant the all-pervading fact of our nature that we are not impressed, made conscious, or mentally alive, without some change of state or impression. 2 An unvarying action on any of our senses is the same as no action at all. 3 An even temperature, such as that enjoyed by the fishes in the tropical seas, leaves the mind an entire blank as

regards heat and cold. 4 We can neither feel nor know without recognising two distinct states. Hence all knowledge is double, or is the knowledge of contrasts or opposites: 5 heavy is relative to light; up supposes down; being awake implies the state of sleep.

6 The applications of the law in the sphere of emotion are chiefly contemplated in what follows. 7 Pleasure and pain are never absolute states; they have reference always to the previous condition. 8 Until we know what that has been in any case, we cannot pronounce upon the efficacy of a present stimulation. 9 We see a person reposing, apparently in luxurious ease; if the state has been immediately consequent upon a protracted and severe exertion, we are right in calling it highly pleasurable. Under other circumstances, it might be quite the reverse. 10 There is an offshoot or modification of the principle, arising out of the operation of habit. 11 Impressions made upon us are greatest when they are absolutely new: after repetition they all lose something of their power; 12 although, by remission and alternative, the causes of pleasure and pain have still a very considerable efficacy. 13 Many of the consequences of this great fact are sufficiently acknowledged, or, if they are not, it is from other causes than our ignorance. 14 The weakness is moral, rather than intellectual, that makes us expect that the first flush of a great pleasure, a newly-attained joy or success, will continue unabated. 15 The poor person, probably, does not overrate the gratification of newly-attained wealth; what you fails to allow for is the deadening effect of an unbroken experience of ease and plenty.

16 The author of "Romola" says of the hero and the heroine, in the early moments of their affection, that they could not look forward to a time when their kisses should be common things. 17 So it is with the attainment of all great objects of pursuit: the first access of good fortune may not disappoint us; 18 but as we are more and more removed from the state of privation, as the memory of the prior experience fades away, so does the vividness of the present

enjoyment. 19 It is the same with changes for the worse: the agony of a great loss is at first overpowering; gradually, however, the system accommodates itself to the new condition, and the severity dies away. 20 What is called on these occasions the "force of custom" is the application of the law of Accommodation, or Relativity modified by habit.

RELATIVITY IN PLEASURES

21 It is a familiar experience of humankind, yet hard to realise upon mere testimony, that the pleasures of rest, repose, retirement, are wholly relative to foregone labour and toil; 22 after the first shock of transition, they are less and less felt, and can be renewed only after a renewal of the contrasting experience. 23 The description, in "Paradise Lost," of the delicious repose of Adam and Eve in Eden is fallacious; the poet credits them with an intensity of pleasure attainable only by the brow-sweating labourer under the curse.

24 The delights of Knowledge are relative to previous Ignorance; for, although the possession of knowledge is in many ways a lasting good, 25 yet the full intensity of the charm is felt only at the moment of passing from mystery to explanation, from blankness of impression to intellectual attainment. 26 This form of the pleasure is sustained only by new acquisitions and new discoveries. 27 Moreover, in the minor forms of the gratification due to knowledge, we never escape the law of relativity; the "power" delights us by relation to our previous impotence. 28 Plato supposed that, in knowledge, we have an example of a pure pleasure, meaning one that had no reference to foregone privation or pain; 29 but such "purity" would be a barren fact, not unlike the pure air of a bladeless and waterless desert. 30 A state of uninterrupted good health, although a prime condition of enjoyment, is of itself a state of neutrality or indifference. 31 The person that has never been ill cannot sing the joys of health; the exultation of

that strain is attainable only by the valetudinarian.

32 These examples have been remarked upon in every age. It is the moral weakness of being carried away by a present strong feeling, as if the state would last for ever, that blinds each of us in turn to the stern reality of the fact. 33 There are, however, numerous instances, coming under Relativity, wherein the indispensable correlative is more or less dropped out of sight and disavowed. 34 These are the proper errors or fallacies of Relativity, a branch of the comprehensive class termed "Fallacies of Confusion". 35 The object of the Panagogue is to exhibit a few of these errors as they occur in questions of practical moment.

36 When it is said, as by Carlyle and others, "speech is silvern, silence is golden," there is implied a condition of things where speech has been in excess; and but for this excess, the assertion is untrue. 37 One might as well talk of the delights of hunger, or of cold, or of solitary confinement, on the ground of there being times when food, warmth, or society may be in excess, and when the opposing states would be a joyful change.

38 The Relativity of Pleasures, although admitted in many individual cases, has often been misconceived. 39 The view is sometimes expressed, that there can be no pleasure without a previous pain; but this goes beyond the exigencies of the principle. 40 We cannot go on for ever with any delight; but mere remission, without any counterpart pain, is enough for our entering with zest on many of our pleasures. 41 A healthy person enjoys own meals without any sensible previous pain of hunger. 42 We do not need to have been miserable for some time as a preparation for the reading of a new poem. 43 It is true that if the sense of privation has been acute, the pleasure is proportionally increased; and that few pleasures of any great intensity grow up from indifference: 44 still, remission and alternation may give a zest for enjoyment without any consciousness of pain.

45 The principle of Comparison is capriciously made use of by Paley, in his account of the elements of

Happiness. 46 He applies it forcibly and felicitously to depreciate certain pleasures-- as greatness, rank, and station-- 47 and withholds its application from the pleasures that he more particularly countenances,-- namely, the social affections, the exercise of the faculties, and health.

SIMPLICITY OF STYLE A RELATIVE MERIT

48 The great praise often accorded to Simplicity of Style, in literature, is an example of the suppression of the correlative in a case of mutual relationship. 49 Simplicity is not an absolute merit; it is frequently a merit by correlation. 50 Thus, if a certain subject has never been treated except in abstruse and difficult terminology, a person of surpassing literary powers, setting it forth in homely and intelligible language, produces a work whose highest praise is expressed by Simplicity. 51 Again, after the last century period of artificial, complex, and highly-wrought composition, the reaction of Cowper and Wordsworth in favour of simplicity was an agreeable and refreshing change, and was in great part acceptable because of the change. 52 It does not appear that Wordsworth comprehended this obvious fact; to him, a simplicity that cost nothing to the composer, and brought no novelty to the reader, had still a transcendent merit.

53 It has been a frequent practice of late years to celebrate the praises of Knowledge. Many eloquent speakers have dilated on the happiness and the superiority of the enlightened and the cultivated person. 54 Now, the correlative or obverse must be equally true: there must be a corresponding degradation and disqualification attaching to ignorance and the want of instruction. 55 This correlative and equally cogent statement is suppressed on certain occasions, and by persons that would not demur to the praises of knowledge: 56 as, when we are told of the native good sense, the untaught sagacity, the admirable instincts of the people,-- that is, of the ignorant or the uneducated. 57 Hence the great value of the

expository device of following up every principle with its counter-statement, the matter denied when the principle is affirmed. 58 If knowledge is a thing superlatively good, ignorance-- the opposite of knowledge-- is a thing superlatively bad. There is no middle standing ground.

59 In the way that people use the argument from Authority, there is often an unfelt contradiction from not adverting to the correlative implication. 60 If I lay stress upon some one's authority as lending weight to my opinion, I ought to be equally moved in the opposite direction when the same authority is against me. 61 The common case, however, is to make a great flourish when the authority is one way, and to ignore it when it is the other way. 62 This is especially the fashion in dealing with the ancient philosophers. Socrates, Plato, and Aristotle are quoted with much complacency when they chime in with a modern view; 63 but, in points where they contradict our cherished sentiments, we treat them with a kind of pity as half-informed pagans. 64 It is not seen that people liable to such gross errors as they are alleged to have committed-- say on Ethics-- are by that fact deprived of all weight in allied subjects, as, for example, Politics-- in which Aristotle is still quoted as an authority.

DIGNITY OF ALL LABOUR ABSURD

65 Many of the sins against Relativity can be traced to rhetorical exaggeration. Some remarkable instances of this can be cited. 66 When a system of ranks and dignities has once been established, there are associations of dignity and of indignity with different conditions and occupations. 67 It is more dignified to serve in the army than to engage in trade; to be a surgeon is more honourable than to be a watchmaker. 68 In this state of things a fervid rhetorician, eager to redress the inequalities of humankind, starts forth to preach the dignity of all labour. 69 The device is a self-contradiction. Make all labour alike dignified, and nothing is dignified; you simply abolish dignity by

depriving it of the contrast that it subsists upon. 70 Pope's lines--

> Honour and shame from no condition rise;
> Act well your part; there all the honour lies--

cannot be exempted from the fallacy of self-contradiction. 71 Differences of condition are made by differences in the degree of honour thereto attached. 72 If every person that did own work well were put on a level, in point of honour, with every other person that did the same; 73 if the gatekeeper of a mansion, by being unfailingly punctual in opening the gate, were to be equally honoured with a great leader of the House of Commons, 74 then, indeed, equality of pay would be the only thing wanted to abolish all differences of condition. 75 There is, no doubt, in society, a quantity of misplaced honour; but so long as there are employments exceptionally arduous, and virtues signally beneficent in their operation, 76 honour is a legitimate spur and reward, and should be graduated according to the desert in each case.

77 In spurring the ardour of youth to studious exertion, it is common to repeat the Homeric maxim, "to supplant every one else, and stand out first". 78 The stimulating effect is undoubted; it is strong rhetorical brandy. Yet only one person can be first, and the exhortation is given simultaneously to a thousand.

JUSTICE ADMIRABLE ONLY IF RECIPROCATED

79 In the discussion and inculcation of the moral duties and virtues, there has been, in all ages, a tendency to suppress correlative facts, and to affirm unconditionally what is true only with a condition. 80 Thus, the admirable nature of Justice, and the happiness of the Just person, are a proper theme to be extolled with all the power of eloquence. It has been so with every civilised people, pagan as well as Christian. 81 In the dialogues of Plato, justice is a prominent subject, and is adorned with the full splendour of his genius. 82 Aristotle, in one of the few moments when he rises to

poetry, pronounces justice "greater than the evening-star or the morning-star". 83 Now all this panegyric is admissible only on the supposition of reciprocal justice. 84 Plato, indeed, had the hardihood to say that the just person is happy in the self, and by reason of own justice, even although others are unjust to you; but the position is untenable. 85 A person is happy in own justice if it procure for you justice in return; as a citizen is happy in own civil obedience, if it gain you protection in return. 86 There are two parties in the case, and the moralist should obtain access to both; 87 you should induce the one to fulfill your share before promising to the other the happiness of justice and obedience.

88 It may be rhetorical, but it is not true, that justice will make a person happy in a society where it is not reciprocated. 89 Justice, in these circumstances, is highly noble, praiseworthy, virtuous; but the applying of these lofty compliments is the proof that it does not bring happiness, and is an attempt to compensate the deficiency. 90 There is a certain tendency, not very great as human nature is constituted, for justice to beget justice in return-- for social virtue on one side to procure it on the other side. 91 This is a certain encouragement to each person to perform own part, in hope that the other party concerned may do the same. 92 Still, the reciprocity occasionally fails, and with that the benefits to the just agent.

93 It is necessary to urge strongly upon individuals, to impress upon the young, the necessity of performing their duty to society; 94 it is equally implied, and equally indispensable, that society should perform its part to them. 95 The suppressing of the correlative obligation of the State to the individual leaves a one-sided doctrine; the motive of the suppression, doubtless, is that society does not often fail of its duties to the individual, 96 whereas individuals frequently fail of their duties to society. This may be the fact generally, but not always. 97 It is not the fact where there are bad laws and corrupt administration. It is not the fact where the restraints on liberty are greater than the exigencies of the State demand. It

is not the fact, so long as there is a single vestige of persecution for opinions. 98 To be thoroughly veracious, for example, in a society that restrains the discussion and expression of opinions, is more than such a society is entitled to.

PLEASURES OF BENEVOLENCE CONDITIONAL

99 The same fallacy occurs in an allied theme,-- the joys of Love and Benevolence. 100 That love and benevolence are productive of great happiness is beyond question; but then the feeling must be mutual, it must be reciprocated. 101 One-sided love or benevolence is a virtue, which is as much as to say it is not a pleasure. 102 The delights of benevolence are the delights of reciprocated benevolence; until reciprocated, in some form, the benevolent person has, strictly speaking, the sacrifice and nothing more. 103 There is a great reluctance to encounter this simple naked truth; to state it in theory, at least, for it is fully admitted in practice. 104 We fence it off by the assumption that benevolence will always have its reward somehow; that if the objects of it are ungrateful, others will make good the defect at last. 105 Now these qualifications are very pertinent, very suitable to be urged after allowing the plain truth, that benevolence is intrinsically a sacrifice, a painful act; 106 and that this act is redeemed, and far more than redeemed, by a fair reciprocity of benevolence. 107 Only such an admission can keep us out of a mesh of contradictions. 108 Like justice in itself, Benevolence in itself is painful; any virtue is pain in the first instance, although, when equally responded to, it brings a surplus of pleasure. 109 There may be acts of a beneficent tendency that cost the performer nothing, or that even may chance to be agreeable; but these examples must not be given as the rule, or the type. 110 It is the essence of virtuous acts, the prevailing character of the class, to tax the agent, to deprive you of some satisfaction to yourself; this is what we must start from; 111 we are then in a position to explain

how and when, and under what circumstances, and with what limitations, the virtuous person, whether your virtue be justice or benevolence, is from that cause a happy person.

112 It is a fallacy of the suppressed relative to describe virtue as determined by the moral nature of God, as opposed to His arbitrary will. 113 The essence of Morality is obedience to a superior, to a Law; where there is no superior there is nothing either moral or immoral. 114 The supreme power is incapable of an immoral act. Parliament may do what is injurious, it cannot do what is illegal. 115 So the Deity may be beneficent or maleficent, He cannot be moral or immoral.

116 Among the various ways, proposed in the seventeenth century, of solving the difficulty of the mutual action of the heterogeneous agencies-- matter and mind-- one was a mode of Divine interference, called the "Theory of Occasional Causes". 117 According to this view, the Deity exerted Himself by a perpetual miracle to bring about the mental changes corresponding to the physical agents operating on our senses-- light, sound. 118 Now in the mode of action suggested there is nothing self-contradictory; but in the use of the word "miracle" there is a mistake of relativity. 119 The meaning of a miracle is an exceptional interference; it supposes an habitual state of things, from which it is a deviation. 120 The very idea of miracle is abolished if every act is to be alike miraculous.

MYSTERY CORRELATES WITH THE INTELLIGIBLE

121 We shall devote the remainder of this exposition to a still more notable class of mistakes due to the suppression of a correlative member in a relative couple-- 122 those, namely, connected with the designation, "Mystery," a term greatly abused, in various ways, and especially by disregarding its relative character. 123 Mystery supposes certain things that are plain, intelligible, knowable, revealed; and, by contrast to these, refers to certain other things that are obscure, unintelligible,

unknowable, unrevealed. 124 When a person's conduct is entirely plain, straightforward, or accounted for, we call that an intelligible case; when we are perplexed by the tortuosities of a crafty, double-dealing person, we say it is all very mysterious. 125 So, in Nature, we consider that we understand certain phenomena: such as gravity, and all its consequences, in the fall of bodies, the flow of rivers, the motions of the planets, the tides. 126 On the other hand, earthquakes and volcanoes are very mysterious; we do not know what they depend upon, how or in what circumstances they are produced.

127 Some of the operations of living bodies are understood,-- as the heart's action in the mechanical propulsion of the blood; others, and the greater number, are mysterious, as the whole process of germination and growth. 128 Now the existence of the contrast between things plainly understood, and things not understood, gives one distinct meaning to the term Mystery. 129 In some cases, a mystery is formed by an apparent contradiction, as in the Theological mystery of Free-will and Divine Foreknowledge; here, too, there is a contrast with the great mass of consistent and reconcilable things. 130 But now, when we are told by sensational writers, that everything is mysterious; 131 that the simplest phenomenon in Nature-- the fall of a stone, the swing of a pendulum, the continuance of a ball shot in the air-- are wonderful, marvellous, miraculous, 132 our understanding is confounded; there being then nothing lain at all, there is nothing mysterious. 133 The wonderful rises from the common; as the lofty is lofty by relation to something lower: 134 if there is nothing common, then there is nothing wonderful; if all phenomena are mysterious, nothing is mysterious; 135 if we are to stand aghast in amazement because three times four is twelve, what phenomenon can we take as the type of the plain and the intelligible? 136 You must always keep up a standard of the common, the easy, the comprehensible, if you are to regard other things as wonderful, difficult, inexplicable.

LOCKE ON THE LIMITS OF THE UNDERSTANDING

137 The real character of a MYSTERY, and what constitutes the Explanation of fact, have been greatly misconceived. 138 The changes of view on these points make up a chapter in the history of the education of the human mind. 139 Perhaps the most decisive turning point was the publication of Locke's "Essay concerning Human Understanding," 140 the motive of which, as stated in the homely and forcible language of the preface, was to ascertain what our understandings can do, what subjects they are fit to deal with, and where they should stop. I quote a few sentences:--

141 "If by this inquiry into the nature of the Understanding, I can discover the powers thereof; how far they reach; to what things they are in any degree proportionate; and where they fail us: 142 I suppose it may be of use, to prevail with the busy mind of human to be more cautious in meddling with things exceeding its comprehension; 143 to stop when it is at the utmost extent of its tether; and to sit down in a quiet ignorance of those things which, upon examination, are proved to be beyond the reach of our capacities." 144 "The candle that is set up in us, shines bright enough for all our purposes. The discoveries we can make with this ought to satisfy us. 145 And we shall then use our Understandings aright, when we entertain all objects in that way and proportion that they are suited to our faculties, and upon those grounds they are capable of being proposed to us." 146 "It is of great use for the sailor to know the length of own line, though you cannot fathom with it all the depths of the ocean."

147 The course of physical science was preparing the same salutary lesson. 148 Locke's great contemporary and friend, Isaac Newton, was his fellow-worker in this tutorial undertaking; 149 nor should Bacon be forgotten, although there is dispute as to the extent and character of his influence. 150 The combined operation of these great leaders of thought was apparent in the altered views of scientific inquirers as to what is competent in research--

what is the proper aim of inquiry. 151 There arose a disposition to abandon the pursuit of mysterious essences and grand pervading unities, and ascertain with precision the facts and the laws of natural phenomena. 152 The study of astronomy was inaugurated in Greenwich Observatory. The experiments of Priestley and of Franklin farther exemplified the eighteenth-century key to the secrets of the universe. 153 The lesson imparted by Newton and Locke and their successors still remains to be carried out and embodied in the subtler inquiries. 154 The bearing upon what constitutes a Mystery, and what constitutes Explanation, or the accounting for appearances, may be expressed thus:--

155 In the first place, the Understanding can never pass out of its own experience-- its acquired knowledge, whether of body or of mind. 156 What we obtain by our various sensibilities to the world about us, and by our self-consciousness, are the foundation, the ABC of everything that we are capable of knowing. 157 We know colours, and we know sound; we know pleasure and pain, and the various emotions of wonder, fear, love, anger. 158 If there be any being endowed with senses different from ours, with that being we can have no communion. 159 If there be any phenomena that escape our limited sensibilities, they transcend the possibility of our knowledge.

160 It is necessary, however, to take account of the combining or constructive aptitudes of the mind. 161 We can go a certain length in putting together our alphabet of sensation and experience into many various compounds. 162 We can imagine a paradise or a pandemonium; but only as made up of our own knowledge of things good and evil. 163 The limits of this constructive power are soon reached. We are baffled to enter into the feelings of our own kindred, when they are far removed in character and circumstances from ourselves. 164 The youth at twenty cannot approximate to the feelings of people unable to comprehend the life of the invalid.

TIME AND SPACE RELATIVE TO OUR FACULTIES

165 To come to the practical applications. The great leading notions called Time and Space are known to us only under the conditions of our own sensibility. 166 Time is made known by all our actions, all our senses, all our feelings, and by the succession of our thoughts; 167 it is experienced as a continuance and a repetition of movement, sight, sound, fear, or any other state of feeling, or of thinking. 168 One motion or sensation is continued longer than another; or it is more frequently repeated after intermission, giving the numerical estimate of time, as in the beats of the pendulum. 169 In these ways we form estimates of seconds, minutes, hours, days. And our constructive faculty can be brought into play to conceive the larger tracts of duration-- a century, or a hundred centuries.

170 Nay, by our arithmetical powers we can put down in cipher, or conceive symbolically-- which is the meagrest of all conceptions-- millions of millions of centuries; 171 these being after all but compounds of our alphabet of enduring or repeated sensations and thoughts. 172 We can suppose this arithmetical process to operate upon past duration or upon future duration, and there is no limit to the numbers that we can write down. 173 But there is one thing that we cannot do; we cannot fix upon a point when Time or succession began, or upon a point when it will cease. 174 That is an operation not in keeping with our faculties; the very supposition is impracticable. 175 We cannot entertain the notion of a state of things wherein the fact of continuance had no place; the effort belies itself. 176 Time is inseparable from our mental nature; whatever we imagine, we must imagine as enduring.

177 Some philosophers have supposed that we must be endowed by nature with the conception of Time, before we begin to exercise our senses; 178 but the difficulty would be to deprive us of that adjunct without extinguishing our mental nature. 179 Give us sensibility, and you cannot withhold the element of Time. 180 The supposition of Kant

and others, that it is implanted in us as an empty form, before we begin to employ our senses upon things, is needless; 181 for as soon as we move, see, hear, think, are pleased or pained, we create time. 182 And our notion of Time in general is exactly what these sensibilities make it, only enlarged by our constructive power already spoken of.

MATTER AND VOID SUPPLEMENTARY

183 While all our senses and feelings give us time, it is our experience of Motion and Resistance,-- the energetic or active side of our nature alone,-- that gives us Space. 184 The simplest feature of Space is the alternation of Resistance and Non-Resistance, of obstructed motion and freedom to move. 185 The hand presses dead upon an obstacle; the obstacle gives way and allows free motion; these two contrasting experiences are the elements of the two contrasting facts-- Matter and Space. 186 By none of the five senses, in their pure and proper character as senses, can we obtain these experiences; 187 and hence at an earlier stage of inquiry into the mind, when our knowledge-giving sensibilities were referred to the five senses, there was no adequate account of the notion of Space or Extension. 188 Space includes more than this simple contrast of the resisting and the non-resisting; it includes what we call the Co-existing or Contemporaneous, 189 the great aggregate of the outspread world, as existing at any moment, a somewhat complicated attainment, which I am not now specially concerned with.

190 It sufficiently illustrates the limitation of our knowledge by our sensibilities, from the nature of space, to fasten attention on the double and mutually supplementing experience of Matter and Void; 191 the one resisting movement, and giving the consciousness of resistance, or dead strain, the other permitting movement, and giving the consciousness of the unobstructed sweep of the limbs or members. 192 Whatever else may be in space, this freedom to move, to soar, to

expatiate-- in contrast to being hemmed in, obstructed, held fast--, is an essential part of the conception, and is formed out of our active or moving sensibilities.

193 Now, as far as movement is concerned, we must be in one of two states;-- we must be putting forth energy without effecting movement, being met by obstacles called matter; 194 or we must be putting forth energy unresisted and effecting movement, which is what we mean by empty space. 195 There is no third position in the matter of putting forth our active energy. 196 Where resistance ends and freedom begins, there is space; where freedom ends, and obstruction begins, there is matter. 197 We find our sentient life to be made up, as regards movement, of a certain number and range of these two alternations; in other words, free spaces and resisting barriers. 198 And we can, by the constructive power already mentioned, imagine other proportions of the two experiences; 199 we can imagine the scope for movement, the absence of obstruction, to be enlarged more and more, to be counted by thousands and millions of miles; but the only terminus or boundary that we can imagine is resistance, a dead obstacle.

200 We are able to conceive the starry spaces widened and prolonged from galaxy to galaxy through enormous strides of increasing amplitude, 201 but when we try to think an end to this career, we can think only of a dead wall. 202 There is no other end of space within the grasp of our faculties; and that termination is not an end of extension; 203 for we know that solid matter, viewed in other ways than as obstructing movement, has the same property of the extended belonging to the empty void. 204 The inference is, that the limitation of our means of knowledge renders altogether incompetent the imagination of an end to either Time or Space. 205 The greatest efforts of our combining faculty cannot exceed the elements presented to it, and these elements contain nothing that would set forth the situation of space ending, and obstruction not beginning.

ARE TIME AND SPACE INFINITE?

206 Under these circumstances, it is an irrevelant enquiry, to ask, Are Time and Space finite or infinite? 207 Many philosophers have put the question, and even answered it. They say Time has no beginning and no end, and Space has no boundaries; or, as otherwise expressed,--Time and Space are Infinite: 208 an answer of such vagueness as to mean anything, from a harmless and proper assertion of the limits of our faculties, up to the verge of extravagance and self-contradiction.

209 When, in fact, people talk of the Infinite in Time and Space, they can point to one intelligible signification; 210 as to the rest, this word is not a subject for scientific propositions, and the attempt at such can lead only to contradictions. 211 The Infinite is a phrase most various in its purport: it is for the most part an emotional word, expressing human desire and aspiration; 212 a word of poetry, imagination, and preaching, not a word to be discussed under science; no intellectual definition would exhibit its emotional force.

213 The second property of our intelligence is, that we can generalise many facts into one. 214 Tracing agreement among the multifarious appearances of things, we can comprehend in one statement a vast number of details. 215 The single law of gravity expresses the fall of a stone, the flow of rivers, the retention of the moon in its circuit round the earth. 216 Now, this generalising sweep is a real advance in our knowledge, an ascent in the matter of intelligence, a step towards centralising the empire of science. 217 What is more, this is the only real meaning of EXPLANATION. A difficulty is solved, a mystery unriddled; when it can be shown to resemble something else; to be an example of a fact already known. 218 Mystery is isolation, exception, or, it may be, apparent contradiction; the resolution of the mystery is found in assimilation, identity, fraternity. 219 When all things are assimilated, so far as assimilation can go, so far as likeness holds, there is an end to

explanation; there is an end to what the mind can do, or can intelligently desire.

GRAVITY NOT A MYSTERY

220 Thus, when Gravity was generalised, by assimilating the terrestrial attraction seen in falling bodies with the celestial attraction of the sun and planets; 221 and when, by fair presumption, the same power was extended to the remote stars; 222 when, also, the law was ascertained, so that the movements of the various bodies could be computed and predicted, there was nothing further to be done; explanation was exhausted. 223 Unless we can find some other force to fraternise with gravity, so that the two might become a still more comprehensive unity, we must rest in gravity as the ultimatum of our faculties. 224 There is no conceivable modification, or substitute, that would better our position. 225 Before Newton, it was a mystery what kept the moon and the planets in their places; the assimilation with falling bodies was the solution.

226 But, say many persons, is not gravity itself a mystery? We say No; gravity has passed through all the stages of legitimate and possible explanation; 227 it is the most highly generalised of all physical facts, and by no assignable transformation could it be made more intelligible than it is. 228 It is singularly easy of comprehension; its law is exactly known; 229 and, excepting the details of calculation, in its more complex workings, there is nothing to complain of, nothing to rectify, nothing to pretend ignorance about; 230 it is the very pattern, the model, the consummation of knowledge. 231 The path of science, as exhibited in modern times, is towards generality, wider and wider, until we reach the highest, the widest laws of every department of things; 232 there explanation is finished, mystery ends, perfect vision is gained.

233 What is always reckoned the mystery by pre-eminence is the union of BODY and MIND. 234 How, then, should we treat this

Mystery according to the spirit of modern thought, according to the modern laws of explanation? 235 The course is to conceive the elements according to the only possible plan, our own sensibility or consciousness; 236 which gives us matter as one class of facts-- extension, inertness, weight, and so on; and mind as another class of facts-- pleasures, pains, volitions, ideas. 237 The difference between these two is total, diametrical, complete; there is really nothing common to the experience of pleasure and the experience of a tree; 238 difference has here reached its acme; agreement is eliminated; there is no higher genus to include these two in one; 239 as the ultimate, the highest elements of knowledge, they admit of 110-fusion, no resolution, no unity. 240 Our utmost flight of generality leaves us in possession of a double, a couple of absolutely heterogeneous elements. 241 Matter cannot be resolved into mind; mind cannot be resolved into matter; each has its own definition; each negatives the other.

242 This being the fact, we accept it, and acquiesce. There is surely nothing to be dissatisfied with, to complain of, in the circumstance that the elements of our experience are, in the last resort, two, and not one. 243 If we had been provided with fifty ultimate experiences, none of them having a single property in common with any other; 244 and if we had only our present limited intellects, we might be entitled to complain of the world's mysteriousness in the one proper acceptation of mystery-- namely, as overpowering our means of comprehension, as loading us with unassimilable facts. 245 As it is, matter, in its commoner aspects and properties, is perfectly intelligible; 246 in the great number and variety of its endowments or properties, it is revealed to us slowly and with much difficulty, and these subtle properties-- the deep affinities and molecular arrangements--- are the mysteries rightly so called. 247 Mind in itself is also intelligible; a pleasure is as intelligible as would be any transmutation of it into the inscrutable essence that people often desiderate. 248 It is one of

the facts of our sensibility, and has a great many facts of its own kindred, which makes it all the more intelligible.

249 The varieties of pleasure, pain, and emotion are very numerous; and to know, remember, and classify them, is a work of labour, a legitimate mystery. 250 The subtle links of thought are also very various, although probably all reducible to a small number; 251 and the ascertaining and following out of these has been a work of labour and time; they have, therefore, been mysterious; mystery and intellectual toil being the real correlatives. 252 The complications of matter and the complications of mind are genuine mysteries; 253 the reducing or simplifying of these complications, by the exertions of thinking people, is the way, and the only way out of the darkness into light.

UNION OF MIND AND BODY

254 But what now of the mysterious union of the two great ultimate facts of human experience? 255 What should the followers of Newton and Locke say to this crowning instance of deep and awful mystery? 256 Only one answer can be given. Accept the union, and generalise it. 257 Find out the fewest number of simple laws, such as will express all the phenomena of this conjoint life. 258 Resolve into the highest possible generalities the connections of pleasure and pain, with all the physical stimulants of the senses-- food, tastes, odours, sounds, lights-- 259 with all the play of feature and of gesture, and all the resulting movements and bodily changes; 260 and when you have done that, you have so far truly, fully, finally explained the union of body and mind.

261 Extend your generalities to the course of the thoughts; determine what physical changes accompany the memory, the reason, the imagination, 262 and express those changes in the most general, comprehensive laws, and you have explained the how and the why brain causes thought, and thought works in brain. 263 There is no other explanation needful, no other

competent, no other that would be explanation. 264 Instead of our being "unfortunate," as is sometimes said, in not being able to know the essence of either matter or mind-- in not comprehending their union; 265 our misfortune would be to have to know anything different from what we do or may know. 266 If there be still much mystery attaching to this linking of the two extreme facts of our experience, it is simply this: that we have made so little way in ascertaining what in one goes with what in the other.

267 We know a good deal about the feelings and their alliances, some of which are open and palpable to all humankind; and we have obtained some important generalities in these alliances. 268 Of the connections of thought with physical changes we know very little: these connections, therefore, are truly and properly mysterious; but they are not intrinsically or hopelessly so. 269 The advancing study of the physical organs, on the one hand, and of the mental functions, on the other, may gradually abate this mystery. 270 And if a day arrive when the links that unite our intellectual workings with the workings of the nervous system and the other bodily organs shall be fully ascertained and adequately generalised, 271 no one thoroughly educated in the scientific spirit of the last two centuries will call the union of mind and body any longer inscrutable or mysterious.

METAPHYSICS AND DEBATING SOCIETIES

Alexander Bain

14 By "Metaphysical Study," or "Metaphysics," I here mean-- what seems intended by the designation in its current employment at present-- the circle of the mental or subjective sciences. 2 The central department of the field is PSYCHOLOGY, and the adjunct to psychology is LOGIC, which has its foundations partly in psychology, but still more in the sciences altogether, whose procedure it gathers up and formulates. 3 The outlying and dependent branches are: the narrower metaphysics or Ontology, Ethics, Sociology,

together with Art or Aesthetics. 4 There are other applied sciences of the department, as Education and Philology.

5 The branches most usually looked upon as the cognate or allied studies of the subjective department of human knowledge are, Psychology, Logic, Ontology, Ethics. 6 The debates in a society like the present will generally be found to revolve in the orbit thus chalked out. 7 It is the sphere of the most animated controversies, and the widest discordance of view. 8 The additional branch most nearly connected with the group is Sociology, which under that name, and under the older title, the Philosophy of History, has opened up a new series of problems, of the kind to divide opinions and provoke debate. 9 A quieter interest attaches to Aesthetics, although the subject is a not unfruitful application and test of psychological laws.

10 My remarks will embrace, first, the aims, real and factitious, in the study of this group of sciences; and next, the polemic conduct of such study, or the utility and management of debating societies, instituted in connection therewith.

PSYCHOLOGY AND LOGIC FUNDAMENTAL

11 The two sciences--PSYCHOLOGY and LOGIC-- I consider the fundamental and knowledge-giving departments. 12 The others are the applications of these to the more stirring questions of human life. 13 Now, the successful cultivation of the field requires you to give at least as much attention to the root sciences as you give to the branch sciences. 14 That is to say, psychology, in its pure and proper character, and logic, in its systematic array, should be kept before the view, concurrently with ontology, ethics, and sociology. 15 Essays and debates tending to clear up and expound systematic psychology and systematic logic should make a full half of the society's work.

16 Does any one feel a doubt upon the point, as so stated? If so, it will be upon you to show that Psychology, in its methodical pursuit, is a needless and

superfluous employment of strength; 17 that the problems of ethics, ontology, can be solved without it-- a hard task indeed, so long as they are unsolved in any way. 18 I have no space for indulging in a dissertation on the value of methodical study and arrangement in the extension of our knowledge, 19 as opposed to the promiscuous mingling of different kinds of facts, which is often required in practice, but repugnant to the increase of knowledge. 20 If you want to improve our acquaintance with the sense of touch, you accumulate and methodise all the experiences relating to touch; 21 you compare them, see whether they are consistent or inconsistent, select the good, reject the bad, improve the statement of one by light borrowed from the others; 22 you mark desiderata, experiments to be tried, or observations to be sought. All that time, you refrain from wandering into other spheres of mental phenomena. 23 You make use of comparison with the rest of the senses, it may be, but you keep strictly to the points of analogy, where mutual lights are to be had. 24 This is the culture of knowledge as such, and is the best, the essential, preparation for practical questions involving the particular subject along with others.

25 To take an example from the question of the Will. I do not object: to the detaching and isolating of the problem of free-will, as a matter for discussion and debate; 26 but I think that it can be handled to equal, if not greater advantage, in the systematic psychology of voluntary power. 27 Those that have never tried it in this last form have not obtained the best vantage-ground for overcoming the inevitable subtleties that invest it.

28 The great problem of External Perception has a psychological place, where its difficulties are very much attenuated, to say the least of it; 29 and, however convenient it may be to treat it as a detached problem, we should carry with us into the discussion all the lights that we obtain while regarding it as it stands among the intellectual powers.

30 It is in systematic Psychology that we are most free to attend to the defining of terms-- without

which a professed science is mere moonshine--, 31 to the formulating of axioms and generalities, to the concatenating and taking stock of all the existing knowledge, and to the appraising of it at its real value. 32 If these things are neglected, there is nothing that I see to constitute a psychology at all.

DISCUSSIONS IN LOGIC PROPER

33 As to the other fundamental science, LOGIC, the same remarks may be repeated. 34 Of debated questions, a certain number pertain properly to logic; yet most of these relate to logic at its points of contact with psychology. 35 Since we have got out of the narrow round of the Aristotelian syllogism, we have agreed to call logic ‘ars artium’, or, better still, ‘scientia scientiarum’, the science that deals with the sciences altogether-- both object sciences and subject sciences. 36 Now this I take to be a study quite apart from psychology in particular, although, as I have said, touching it at several points. 37 It reviews all science and all knowledge, as to its structure, method, arrangement, classification, probation, enlargement. It deals in generalities the most general of any. 38 By taking up what belongs to all knowledge, it seems to rise above the matter of knowledge to the region of pure form; 39 it demands, therefore, a peculiar subtlety of handling, and may easily land us, as we are all aware, in knotty questions and quagmires. 40 Now what I have to repeat in this connection is, that you should, in your debates, overhaul portions or chapters of systematic logic, with a view to present the difficulties in their natural position in the subject. 41 You might, for example, take up the question as to the Province of logic, with its divisions, parts, and order-- all which admit of many various views-- and bring forward the vexed controversies under lights favourable to their resolution. 42 Regarding logic as an aid to the faculties in tackling whatever is abstruse, you should endeavour to cultivate and enhance its powers, in this particular, by detailed

exposition and criticism of all its canons and prescriptions. 43 The department of Classification is a good instance; a region full of delicate subtleties as well as "bread-and-butter" applications.

44 It is in this last view of logic that we can canvass philosophical systems upon the ground of their method or procedure alone. 45 Looking at the absence, in any given system, of the arts and precautions that are indispensable to the establishment of truth in the special case, we may pronounce against it, à-priori; 46 we know that such a system can be true only by accident, or else by miracle. 47 We may reasonably demand of a system-builder-- Are you in the narrow way that leadeth to truth, or in the broad way that leadeth somewhere else?

48 I have said that I consider the connection between Logic and Psychology to be but slender, although not unimportant. 49 The amount and nature of this connection would reward a careful consideration. 50 There would be considerable difficulty in seeing any connection at all between the Aristotelian Syllogism and psychology, 51 but for the high-sounding designations appended to the notion and the proposition-- simple apprehension and judgment-- of which I fail to discover the propriety or relevance. 52 I know that Grote gave a very profound turn to the employment of the term "judgment" by Aristotle, as being a recognition of the relativity of knowledge to the affirming mind.

53 I am not to say, absolutely, "Ice is cold"; I am to say that, to the best of my judgment or belief, or in so far as I am concerned, ice is cold. 54 This, however, has little to do with the logic of the syllogism, and not much with any logic. 55 So, when we speak of a "notion," we must understand it as apprehended by some mind; 56 but for nearly all purposes, this is assumed tacitly; it need not appear in a formal designation, which, not being wanted, is calculated to mislead.

METAPHYSICS

APPLIED OR DERIVATIVE SCIENCES

57 With these remarks on the two fundamental sciences of our group, I now turn to the applied or derivative sciences, wherein the great controversies stand out most conspicuous, which, in fact, exist for the purpose of contention--Ontology and Ethics. 58 These branches were in request long before the mother sciences--psychology and logic-- came into being at all. 59 They had occupied their chief positions without consulting the others, partly because these were not there to consult, and partly because they were not inclined to consult any extraneous authority. 60 By Ontology we may designate the standing controversies of the intellectual powers--perception, innate ideas, nominalism versus realism, and noumenon versus phenomenon. 61 I am not going to pronounce upon these questions; I have already recommended the alternative mode of approaching them under systematic psychology and logic; 62 and I will now regard them as constituents of the fourfold enumeration of the metaphysical sciences.

63 The Germans may be credited for teaching us, or trying to teach us, to distinguish "bread and butter" from what passes beyond, transcends bread and butter. 64 With them the distinction is thoroughly ingrained, and comes to hand at a moment's notice. 65 If I am to review in detail what may be considered the practical or applied departments of logic and psychology, I am in danger of trenching on their "bread-and-butter" region. 66 Before descending, therefore, into the larder, let us first spend a few seconds in considering psychology as the pursuit of truth in all that relates to our mental constitution. 67 If difficulty be a stimulus to the human exertions, it may be found here. 68 To ascertain, fix, and embody the precise truth in regard to the facts of the mind is about as hard an undertaking as could be prescribed to a human. 69 But this is another way of saying that psychology is not a very advanced science; 70 is not well stored with clear and certain doctrines; and is unable, therefore, to confer any

very great precision on its dependent branches, whether purely speculative or practical. 71 In a word, the greatest modesty or humility is the deportment most becoming to all that engage in this field of labour, even when doing their best; 72 while the same virtues in even greater measure are due from those engaging in it without doing their best.

73 It must be admitted, however, that the highest evidence and safeguard of truth is application. In every other science, the utility test is final. 74 The great parent sciences-- mathematics, physics, chemistry, physiology-- have each a host of filial dependents, in close contact with the supply of human wants; 75 and the success of the applications is the testimony to the truth of the sciences applied. 76 Thus, although we may not narrow the sphere of truth to bread and butter, yet we have no surer test of the truth itself. 77 Our trade requires navigation, and navigation verifies astronomy; and, but for navigation, we may be pretty confident that astronomy would now have very little accuracy to boast of.

78 To come then to the practical bearings or outgoings of psychology, assisted by logic. My contention is that the parent sciences and the filial sciences should be carried on together; 79 that theses should be extracted by turns from all; that the lights thus obtained would be mutual. 80 I will support the position by a review of the subjects thus drawn into the metaphysical field.

PROBLEMS OF EDUCATION

81 Foremost among these applied sciences I would place EDUCATION, the subject of the day. 82 The priority of mention is due not so much to its special or pre-eminent importance, as to its being the most feasible and hopeful of the practical applications of conjoined psychology and logic. 83 I say this, however, with a more express eye to intellectual education. I deem it quite possible to frame a practical, science applicable to the training of the intellect that shall be precise and definite in a very considerable measure. 84 The elements that

make up our intellectual furniture can be stated with clearness; 85 the laws of intellectual growth or acquisition are almost the best ascertained generalities of the human mind; 86 even the most complicated studies can be analysed into their components, partly by psychology and partly by the higher logic. 87 In a word, if we cannot make a science of education, as far as Intellect is concerned, we may abandon metaphysical study altogether.

88 I do not speak with the same confidence as to moral education. There has long been in existence a respectable rule-of-thumb practice in this region, the result of a sufficiently wide experience. 89 There are certain psychological laws, especially those relating to the formation of moral habits, that have a considerable value; 90 but to frame a theory of moral education, on a level in a point of definiteness with the possible theory of intellectual education, is a task that I should not like to have imposed upon me. 91 In point of fact, two problems are joined in one, to the confusion of both. 92 There is first the vast question of moral control, which stretches far and wide over many fields, and would have to be tracked with immense labour: 93 it belongs to the arts of government; it comes under moral suasion, as exercised by the preacher and orator; it even implicates the tact of diplomacy. 94 I do not regard this as a properly educational question-- although it refers to an art that every teacher must try to master--; 95 that is to say, its solution is not connected with education processes strictly so called. 96 The second problem of moral education is the one really within the scope of the subject-- the problem of fixing moral bents or habits, when the right conduct is once initiated. 97 On this head, some scientific insight is attainable; and suggestions of solid value may in time accrue, although there never can be the precision attainable in the intellectual region.

98 I will next advert to the applied science of Art or Aesthetics, long a barren ground, so far as scientific handling was concerned, but now a land of promise. 99 The old thesis, "What is Beauty?" a good debating society topic, is, I hope,

past contending about. 100 The numerous influences that concur in works of art, or in natural beauty, present a fine opening for delicate analysis; 101 at the same time, they implicate the vaguest and least advanced portion of psychology-- the Emotions. 102 The German philosophers have usually ranked aesthetics as one of the subjective sciences; but, it is only of late that the department has taken shape in their country. 103 Lessing gave a great impulse to literary art, and originated a number of pregnant suggestions; and the German love of music has necessarily led to theories as well as to compositions.

104 We are now in the way to that consummation of aesthetics which may be described as containing (1) a reference to psychology as the mother science, 105 (2) a classification, comparison, and contrast of the fine arts themselves, and (3) an induction of the principles of art composition from the best examples. 106 Anything like a thorough sifting of fine-art questions would strain psychology at every point-- senses, emotions, intellect; and, if criticism is to go deep, it must ground upon psychological reasons. 107 Now the mere artist can never be a psychologist; the art critic may, but seldom will; hence, as they will not come over to us, some of us must go over to them. 108 The Art discussion of the greatest fountains of human feeling-- love and anger-- would react with advantage upon the very difficult psychology of these emotions, so long the sport of superficiality.

AESTHETICS: HEDONICS

109 But I hold that aesthetics is but a corner of a larger field that is seldom even named among the sciences of mind; 110 I mean human happiness as a whole, "eudaemonics," or "hedonics," or whatever you please to call it. 111 That the subject is neglected, I do not affirm; but it is not cultivated in the proper place, or in the proper light-giving connection-- that is to say, under the psychology of the human feelings. 112 It should have at once a close reference to psychology, and an

independent construction; while either in comprehending aesthetics, or in lying side by side with that, it would give and receive illumination. 113 The researches now making into the laws and limits of human sensibility, if they have any value, ought to lead to the economy of pleasure and the abatement of pain. 114 The analysis of sensation and of emotion points to this end. Whoever raises any question as to human happiness should refer it, in the first instance, to psychology; 115 in the next, to some general scheme that would answer for a science of happiness; 116 and, thirdly, to an induction of the facts of human experience; the three distinct appeals correcting one another. 117 If psychology can contribute nothing to the point, it confesses to a desideratum for future inquirers.

HEDONICS SEPARATE FROM ETHICS

118 I am not at all satisfied with the coupling of happiness with ethics, as is usually done. Ethics is the sphere of duty; happiness is mentioned only to be repressed and discouraged. 119 This is not the situation for unfolding all the blossoms of human delight, nor for studying to allay every rising uneasiness. 120 You would be a rare ethical philosopher that would permit full scope to such an operation within your grounds; neither Epicurus nor Bentham could come up to this mark. 121 But even if the thing were permitted, the lights are not there; 122 it is only by combining the parent psychology and the hedonic derivative, that the work can be done. 123 It is neither disrespect nor disadvantage to duty, that it is not mentioned in the department until the very end. 124 To cultivate happiness is not selfishness or vice, unless you confine it to self; and the mere act of inquiring does not so confine it. 125 If you are in other respects a selfish person, you will apply your knowledge for your own sole behoof; 126 if you are not selfish, you will apply it for the good of your fellows also, which is another name for virtue.

127 But the obstacles to a science of happiness are not solely clue to

the gaps and deficiencies in our psychological knowledge; they are equally owing to the prevailing terrorism in favour of self-denial at all hands. 128 Many of the maxims as to happiness would not stand examination if people felt themselves free to discuss them. 129 You must work yourselves into a fervour of revolt and defiance, before you call in question Paley's declaration that "happiness is equally distributed among all orders of the community". 130 I do not know whether I should wonder most at the cheerful temperament or the complacent optimism of Adam Smith, 131 when he asks, "What can be added to the happiness of the person who is in health, who is out of debt, and has a clear conscience?" 132 When the greatest philosophers talk thus, what is to be expected from the unphilosophic mob? 133 The dependence of health on activity is always kept very loose, it may be for the convenience of shutting our mouths against complaints of being overworked. To render this dependence precise is a matter of pure psychology.

SOCIOLOGY

134 Before coming to Ethics I must, as a preparation, view another derivative branch of psychology, the old subject of politics and society, under its new name, SOCIOLOGY. 135 It is obvious that all terms used in describing social facts and their generalities are terms of mind: command and obedience, law and right, order and progress, are notions made up of human feelings, purposes, and thoughts.

136 Sociology is usually studied in its own special field, and nowhere else; 137 that is to say, the sociologist employs the self in observing and comparing the operations of societies under all varieties of circumstances, and in all historic ages. 138 The field is essentially human nature, and the laws arrived at are laws of human nature. 139 A consummate sociologist is not often to be found; the really great theorists in society could be counted on one's fingers. 140 Some of them have been psychologists as well; I need mention only Aristotle, Hobbes, Locke, Hume, the Mills. 141

Others as Vico, Montesquieu, Millar, Condorcet, Auguste Comte, De Tocqueville, have not independently studied the mind on the broad psychological basis. 142 Now the bearings on sociology of a pure psychological preparation can be convincingly shown. 143 The laws of society, if not the merest empiricisms, are derivative laws of the mind; 144 hence a theorist cannot be trusted with the handling of a derivative law, unless you knows, as well as can be known, the simple or constituent laws. 145 All the elements of human character crop up in human's social relations; 146 in the foreground are their self-interest or sense of self-preservation, together with their social and anti-social promptings; 147 a little farther back are their active energy, their intelligence, their artistic feelings, and their religious susceptibilities. 148 Now all these should be broadly examined as elements of the mind, without an immediate reference to the political machine.

149 Of course, the social feelings need a social situation, and cannot be studied without that; 150 but there are many social situations that give scope for examining them, besides what is contemplated in political society; 151 and the psychologist proper ought to avail the self of all the opportunities of rendering the statement of these various elements precise. 152 For this purpose, your chief aim is the ultimate analysis of the various faculties and feelings. 154 This analysis nobody but yourself cares to institute; and yet a knowledge of the ultimate constitution of an emotional tendency is one of the best aids in appreciating its mode of working. 155 Without a good preliminary analysis of the social and anti-social emotions, for example, you are almost sure to be counting the same thing twice over, or else confounding two different facts under one designation. 156 On the one hand, the precise relationship of the states named love, sympathy, disinterestedness; and, on the other hand, the common basis of domination, resentment, pride, egotism,-- should be distinctly cleared up, as is possible only in psychological study strictly so

called. 157 The workings of the religious sentiment cannot be shown sociologically, without a previous analysis of the constituent emotions.

SOCIOLOGICAL FOUNDATIONS OF ETHICS

158 An allusion so very slender to so vast a subject as sociology would be a waste of words, but for the conviction, that through sociology is the way to the great field of Ethics. 159 This is to reverse the traditional arrangement-- ethics, politics, or government-- followed even by Bentham. 160 The lights of ethics are, in the first instance, psychological; its discussions presuppose a number of definitions and distinctions that are pure psychology. 161 But before these have to be adduced, the subject has to be set forth as a problem of sociology. 162 "How is the King's government to be carried on?" "How is society to be held together?" Is the first consideration; and the sociologist-- as constitution-builder, administrator, judge-- is the person to grapple with the problem. 163 It is with you that law, obligation, right, command, obedience, sanction, have their origin and their explanation. 164 Ethics is an important supplement to social or political law. But it is still a department of law. In any other view it is a maze, a mystery, a hopeless embroilment.

165 That ethics is involved in society is of course admitted; what is not admitted is, that ethical terms should be settled under the social science in the first place. 166 I may refer to the leading term "law," whose meaning in sociology is remarkably clear; in ethics remarkably the reverse. 167 The confusion deepens when the moral faculty is brought forward. In the eye of the sociologist, nothing could be simpler than the conception of that part of our nature that is appealed to for securing obedience. 168 You assumes a certain effort of the intelligence for understanding the signification of a command or a law; 169 and, for the motive part, you counts upon nothing but volition in its most ordinary form--

the avoidance of a pain. 170 Intelligence and Will, in their usual and recognised workings, are all that are required for social obedience; 171 law is conceived and framed exactly to suit the every-day and every-hour manifestations of these powers. 172 The lawgiver does not speak of an obedience-faculty, nor even of a social-faculty. 173 If there were in the mind a power unique and apart, having nothing in common with our usual intelligence, and nothing in common with our usual will or volition, 174 that power ought to be expressed in terms that exclude the smallest participation of both knowledge and will; it ought to have a form special to itself, and not the form:--" Do this, and ye shall be made to suffer".

175 I am quite aware that there are elements in ethics not included in the problem of social obedience; 176 what I contend for is, that the ground should be cleared by marking out the two provinces, as is actually done by a very small number of theorists, of whom John Austin is about the best example.

177 The ethical philosopher, from not building on a foregone sociology, is obliged to extemporise, in a paragraph, the social system; 178 just as the physical philosopher would, if you had no regularly constructed mathematics to fall back upon, but had to stop every now and then to enunciate a mathematical theorem.

179 The question of the ethical end should first appear as the question of the sociological end. For what purpose or purposes is society maintained? 180 All the ethical difficulties are here met by anticipation, and in a form much better adapted to their solution. 181 It is from the point of view of the social ruler, that you learn reserve, moderation, and sobriety in your aims; 182 you learn to think that something much less than the Utopias-- universal happiness and universal virtue-- should be propounded; 183 you find that a definite and limited province can be assigned, separating what the social power is able to do, must do, and can advantageously do, from what it is unable to do, need not do, and cannot with advantage do; 184 and this or a similar demarcation is reproducible in ethics.

PRECEPTS OF ETHICS MAINLY SOCIAL

185 The precepts of ethics are mainly the precepts of social authority; at all events the social precepts and their sanctions have the priority in scientific method. 186 Some of the highest virtues are sociological; patriotic self-sacrifice is one of the conditions of social preservation. 187 The inculcation of this and of many other virtues would not appear in ethics at all, or only in a supplementary treatment, if social science took its proper sphere, and fully occupied that sphere.

188 Once more. The great problem of moral control, which I would remove entirely from a science of education, would be first dealt with in Sociology. 189 It there appears in the form of the choice and gradation of punishments, in prison discipline, and in the reformation of criminals,-- 191 all which have been made the subject of enlightened, not to say scientific, treatment. 191 It is in the best experience in those subjects that I would begin to seek for lights on the comprehensive question. 192 I would next go to diplomacy for the arts of delicate address in reconciling opposing interests; 193 after which I would look to the management of parties and conflicting interests in the State. 194 I would farther inquire how armies are disciplined, and subordination combined with the enthusiasm that leads to noble deeds.

195 There is an abundant field for the application of pure psychology to ethics, when it takes its own proper ground. 196 The exact psychological character of disinterested impulse needs to be assigned; 197 and, if that impulse can be fully referred to the sympathetic or social instincts and habits, the supposed moral faculty is finally eviscerated of its contents for all ethical purposes.

198 So far I have exemplified what seems to me real or genuine aims and applications of metaphysical study. I now proceed to the objects that are more or less factitious. 199 We are here on delicate ground, and run the risk of discrediting our pursuit, as regards the very things that in the eyes of many people make its value.

200 First, then, as psychology involves all our sensibilities, pleasures, affections, aspirations, capacities, it is thought on that ground to have a special nobility and greatness, and a special power of evoking in the student the feelings themselves. 201 The mathematician, dealing with conic sections, spirals, and differential equations, is in danger of being ultimately resolved into a function or a co-efficient; 202 the metaphysician, by investigating conscience, must become conscientious; driving fat oxen is the way to grow fat.

HUMAN'S RELATIONS TO THE INFINITE

203 But to pass to a far graver application. It has usually been supposed that metaphysical theory is more especially akin to the speculation that mounts to the supernatural and the transcendental world. 204 "Human's relations to the infinite" is a frequent phrase in the mouth of the metaphysician. 205 Metaphysics is supposed to be "philosophy" by way of eminence; and philosophy in the large sense has not merely to satisfy the curiosity of the human mind, 206 it has to provide scope for its emotions and aspirations; in fact, to play the part of theology. 207 In times when the prevailing orthodox beliefs are shaken, some scheme of philosophy is brought forward to take their place.

208 If I understand aright the drift of the German metaphysical systems for century back, they all more or less propose to themselves to supply the same spiritual wants as religion supplies. 209 In our own country, such of us as are not under German influence put the matter differently; but we still consider that we have something to say on the "highest questions". 210 We are apt to believe that on us more than on any other class of thinkers, does it depend whether the prevailing theology shall be upheld, impugned, or transformed. 211 The chief weapons of the defenders of the faith are forged in the schools of metaphysics. Locke and Butler, Reid, Stewart and Brown are theological authorities. 212 And when theology is attacked, its metaphysical

buttresses have to be assailed as the very first thing. 213 If these are declared unsound, either it must fall, or it must change its front. 214 It is Natural Theology, more particularly, that is thus allied to metaphysics; yet, not exclusively; 215 for the defence of Revelation by miracles involves at the outset a point of logic.

216 Now I do not mean to say, that this is a purely factitious and ill-grounded employment of the metaphysical sciences. 217 I fully admit that the later defences of theology, as well as the attacks, have been furnished from psychology, logic, ethics, and ontology. 218 The earliest beliefs in religion, the greatest and strongest convictions, had little to do with any of these departments of speculation. 219 But when simple traditionary faith gave place to the questionings of the reason, the basis of religion was transferred to the reason-built sciences; and metaphysics came in for a large share in the decision.

METAPHYSICS AND THEOLOGY

220 What I maintain is, that there is something factitious in the degree of prominence given to metaphysics in this great enterprise; 221 that its pretentions are excessive, its importance over-stated; and when most employed for such a purpose, it is least to be trusted. 222 Theological polemic is only in part conducted through science; and physical science shares equally with moral. 223 The most serious shocks to the traditional orthodoxy have come from the physical sciences. 224 The argument from Design has no doubt a metaphysical or logical element-- the estimate of the degree of analogy between the universe and a piece of human workmanship; 225 but the argument itself needs a scientific survey of the entire phenomena of Nature, both matter and mind. 226 Our Bridgewater Treatises proceeded upon this view; they embraced the consideration of the whole circle of the sciences, as bearing on the theological argument. 227 The scheme was so far just and to the purpose; the

obvious drawback to the value of the Treatises lay in their being special pleadings, backed by a fee of a thousand pounds to each writer for maintaining one side. 228 If a similar fee had been given to nine equally able writers to represent the other side, the argument from design would have been far more satisfactorily sifted than by the exclusively metaphysical criticism of Kant.

229 When theology is supported exclusively by such doctrines as-- an independent and immaterial soul, a special moral faculty, and what is called free-will,-- the metaphysician is a person of importance in the contest; 230 you are powerful either to uphold or to subvert the fabric. 231 But, if these were ever to constitute the chief stronghold of the faith, its tenure would not be very secure. 232 It is only a metaphysician, however, that believes or disbelieves in metaphysical grounds alone; such a person as Cousin, no doubt, rests own whole spiritual philosophy on this foundation. 233 But the great mass will either adhere to religion in spite of metaphysical difficulties, or else abandon it notwithstanding its metaphysical evidences. 234 An eminent man now departed said in my hearing, that he was a believer in Christianity until he became acquainted with geology, 235 when, finding the first chapter of Genesis at variance with geological doctrines, he applied to the Bible the rule ‘falsus in uno, falsus in omnibus,’ and thenceforth abandoned his old belief. 236 I never heard of any one that was so worked upon by a purely metaphysical argument.

237 The aspect of theological doctrine that has come most to the front of late is the question of the Divine goodness, as shown in the plan of the universe. 238 Speculations are divided between optimism and pessimism. How shall we decide between these extremes, or, if repudiating both, how shall we fix the mean? 239 Is a metaphysician more especially qualified to find out the truth? I hardly think so. I believe you could contribute, with others, to such a solution as may be possible. 240 You have, we shall suppose, surveyed closely the compass of the human sensibilities, and is able

to assign, with more than common precision, what things operate on them favourably or unfavourably. 241 So far good. Then, as a logician, you are more expert at detecting bad inferences in regard to the form of reasoning; 242 but whether certain allegations of fact are well or ill founded, you may not be able to say, at least out of your own department. 243 If a mixed commission of ten were nominated to adjudicate upon this vast problem, metaphysics might claim to be represented by two.

FILLING THE THEOLOGICAL VOID

244 Least of all, do I understand the claims made on behalf of this department to supply the spiritual void in case the old theology is no longer accredited. 245 When one looks closely at the stream and tendency of thought, one sees a growing alliance and kinship between religion and poetry or art. 246 There is, as we know, a dogmatic, precise, severe, logical side of theology, by which creeds are constructed, religious tests imposed, and belief made a matter of legal compulsion. 247 There is also a sentimental, ideal, imaginative side that resists definition, that refuses dogmatic prescription, and seeks only to satisfy spiritual needs and emotions. 248 Metaphysics may no doubt take a part in the dogmatic or doctrinal treatment, but it must qualify itself by biblical study, and become altogether theology.

249 In the other aspect, metaphysics, as I conceive it, is unavailing; the poet is the proper medium for keeping up the emotional side, under all transformations of doctrinal belief. 250 But as conceived by others, metaphysics is philosophy and poetry in one, to which I can never agree. 251 The combination of the two, as hitherto exhibited, has been made at the expense of both. 252 The leading terms of philosophy-- reason, spirit, soul, the ideal, the infinite, the absolute, phenomenal truth, being, consciousness-- are lubricated with emotion, and thrown together in ways that defy the understanding. 253 The unintelligible, which ought

to be the shame of philosophy, is made its glory.

254 These remarks prepare for the conclusion that I arrive at as to the scope of metaphysics with reference to the higher questions. 255 That it has bearings upon these questions I allow; and those bearings are legitimately within the range of metaphysical debates. 256 But I make a wide distinction between metaphysical discussion and theological discussion; and do not consider that they can be combined to advantage. 257 In the great latitude of free inquiry in the present day, theology is freely canvassed, and societies might be properly devoted to that express object; 258 but I cannot see any benefit that would arise by a philosophical society undertaking, in addition to its own province, to raise the questions belonging to theology. 259 I am well aware that there is one society of very distinguished persons in the metropolis, calling itself metaphysical, that freely ventures upon the perilous seas of theological debate. 260 No doubt good comes from any exercise of the liberty of discussion, so long restrained in this region; yet, I can hardly suppose that purely metaphysical studies can thrive in such a connection. 261 Many of the members must think far more of the theological issues than of the cultivation of mental and logical science; and a purely metaphysical debate can seldom be pursued with profit under these conditions.

POLEMICS IN GREECE

262 I now pass to the POLEMICAL handling of the metaphysical subjects. We owe to the Greeks the study of philosophy through methodised debate; 263 and the state of scientific knowledge in the age of the early Athenian schools was favourable to that mode of treatment. 264 The conversations of Socrates, the Dialogues of Plato, and the Topics of Aristotle, are the monuments of Greek contentiousness, 265 turned to account as a great refinement in social intercourse, as a stimulus to individual thought, and a means of advancing at least the speculative departments of knowledge. 266 Grote, both in his "Plato," and in

his "Aristotle," while copiously illustrating all these consequences, has laid extraordinary stress on still another aspect of the polemic of Socrates and Plato, 267 the aspect of free-thought, as against venerated tradition and the received commonplaces of society. 268 The assertion of the right of private judgment in matters of doctrine and belief, was, according to Grote, the greatest of all the fruits of the systematised negation begun by Zeno, and carried out in the "Search Dialogues" of Plato. 269 In the "Exposition Dialogues" it is wanting; and in the "Topica," where Eristic is reduced to method and system by one of Aristotle's greatest logical achievements, the freethinker's wings are very much clipt; the execution of Socrates probably had to answer for that. 270 It is to the Platonic dialogues that we look for the full grandeur of Grecian debate in all its phases. 271 The Plato of Grote is the apotheosis of Negation; it is not a philosophy so much as an epic; the theme--"The Noble Wrath of the Greek Dissenter".

272 At all times, there is much that has to be achieved by solitary thinking. 273 Some definite shape must be given to our thoughts before we can submit them to the operation of other minds; the greater the originality, the longer must be the process of solitary elabouration. 274 The "Principia" was composed from first to last by recluse meditation; 275 probably the attempt to discuss or debate any parts of it would have only fretted and paralysed the author's invention. 276 Indeed, after an enormous strain of the constructive intellect, a person may be in no humour to have own work carped at, even to improve it. 277 In the region of fact, in observation and experiment, there must be a mass of individual and unassisted exertion. 278 The use of allies in this region is to check and confirm the accuracy of the first observer.

279 Again, an inquirer, by dint of prolonged familiarity with a subject, may be own best critic; you may be better able to detect flaws than any one you could call in. 280 This is another way of stating the superiority of a particular individual over all others in the same walk. 281 Such

a monarchical position as removes a person alike from the rivalry and from the sympathy of own fellows, is the exception; mutual criticism and mutual encouragement are the rule. 282 The social stimulants are of avail in knowledge and in truth as well as everything else.

283 A comparison of the state of speculation in the golden age of debate, with the state of the sciences in the present day, both metaphysical and physical, shows us clearly enough, what are the fields where polemic is most profitable. 284 I set aside the struggles of politics and theology, and look to the scientific form of knowledge, which is, after all, the type of our highest certainty everywhere. 285 Now, undoubtedly, it is in classifying, generalising, defining, and in the so-called logical processes-- induction and deduction-- that a person can be least left to the self. 286 Until many people have gone over the same field of facts, a classification, a definition, or an induction, cannot be held as safe and sound. 287 In modern science, there are numerous matters that have passed through the fiery furnace of iterated criticism, seven times purified; 288 but there are, attaching to every science, a number of things still in the furnace. 289 Most of all does this apply to the metaphysical or subject sciences, where, according to the popular belief, nothing has yet passed finally out of the fiery trial. 290 In psychology, in logic, in eudaemonics, in sociology, in ethics, the facts are nearly all around our feet; the question is how to classify, define, generalise, express them. 291 This was the situation of Zeno, Socrates, and Plato, for which they invoked the militant ardour of the mind. 292 Human, they saw, is a fighting being; if fighting will do a thing, you will do it well.

MOST USEFUL CLASSES OF DEBATES

293 In conformity with this view, the foremost class of debates, and certainly not the least profitable, are such as discuss the meanings of important terms. 294 The genius of Socrates perceived that this was the beginning of all valid

knowledge, and, in seeing this, laid the foundation of reasoned truth. 295 I need not repeat the leading terms of metaphysical philosophy; but you can at once understand the form of proceeding by such an instance as "consciousness," 296 debated so as to bring out the question whether, as Hamilton supposed, it is necessarily grounded on knowledge.

297 Next to the leading terms are the broader and more fundamental generalities: for example, the law of relativity; 298 the laws of memory and its conditions, such as the intensity of the present consciousness; Hamilton's inverse relationship of sensation and perception. These are a few psychological instances. 299 The value of a debate on any of these questions depends entirely upon its resolving itself into an inductive survey of the facts, and such surveys are never without fruit.

300 A debating society that includes logic in its sphere should cultivate the methods of debate; setting an example to other societies and to humankind in general. 301 The "Topica" of Aristotle shows an immensity of power expended on this object, doubtless without corresponding results. 302 Nevertheless the attempt, if resumed at the present day, with our clearer and wider views of logical method, would not be barren. 303 This is too little thought of by us; and we may say that polemic, as an art, is still immature. 304 The best examples of procedure are to be found in the Law Courts, some of whose methods might be borrowed in other debates. 305 For one thing, I think that each of the two leaders should provide the members beforehand with a synopsis of the leading arguments or positions to be set forth in the debate. 306 This, I believe, should be insisted on everywhere, not even excepting the debates of Parliament.

307 It is the custom of debating societies to alternate the Debate and the Essay: a very important distinction, as it seems to me; and I will endeavour to indicate how it should be maintained. 308 Frequently there is no substantial distinction observed; an essay is simply the opening of a debate, and a debate the criticism of an

essay. 309 I should like to see the two carried out each on its own principle, as I shall now endeavour to explain.

THE DEBATE: A FIGHT FOR MASTERY

310 The Debate is the fight for mastery as between two sides. The combatants strain their powers to say everything that can be said so as to shake the case of their opponents. 311 The debate is a field-day, a challenge to a trial of strength. 312 Now, while I admit that the intellectual powers may be quickened to unusual perspicacity under the sound of the trumpet and the shock of arms, 313 I also see in the operation many perils and shortcomings, when the subject of contest is truth. 314 In a heated controversy, only the more glaring and prominent facts, considerations, doctrines, distinctions, can obtain a footing. 315 Now truth is the still small voice; it subsists often upon delicate differences, unobtrusive instances, fine calculations. 316 Whether or not human is a wholly selfish being, may be submitted to a contentious debate, because the facts and appearances on both sides are broad and palpable; 317 but whether all our actions are, in the last resort or final analysis, self-regarding, is almost too delicate for debate. 318 Chalmers upholds, as a thesis, the intrinsic misery of the vicious affections: there could not be a finer topic of pure debate.

319 My conception of the Essay, on the other hand, is that it should represent amicable co-operation, with an eye to the truth. 320 By it you should rise from the lower or competitive, to the higher or communistic attitude. There may be a loss of energy, but there is a gain in the manner of applying it. 321 The essayist should set the self to ascertain the truth upon a subject; you should not be anxious to make a case. 322 The listeners, in the same spirit, should welcome all your suggestions, help you out where you are in difficulties, be indulgent to your failings, endeavour to see good in everything. 323 If there be a real occasion for debate, it should be purposely forborne and reserved.

324 In propounding subjects, the respective fitness for the debate and for the essay might be taken into account.

CO-OPERATIVE DISCUSSION IN THE ESSAY

325 When questions have been often debated without coming nearer to a conclusion, it should be regarded as a sign that they are too delicate and subtle for debate. 326 A trial should then be made of the amicable or co-operative treatment represented by the Essay. 327 The Freedom of the Will might, I think, be adjusted by friendly accommodation, but not by force of contention. 328 External Perception is beyond the province of debate. It is fair and legitimate to try all problems by debate, in the first instance, because the excitement quickens the intelligence, and leads to new suggestions; 329 but if the question involves an adjustment of various considerations and minute differences, the contending sides will be contentious still.

330 A society that really aims at the furtherance of knowledge, might test its operations by now and then preparing a report of progress; 331 setting forth what problems had been debated, what themes elucidated, and with what results. 332 It would be very refreshing to see a candid avowal that after several attempts-- both debate and essay-- some leading topic of the department remained exactly where it stood at the outset. 333 After such a confession, the Society might well resolve itself into a Committee of the Whole House, to consider its ways, and indeed its entire position, with a view to a new start on some more hopeful track.

334 My closing remark is, as to avoiding debates that are in their very nature interminable. 335 It is easy to fix upon a few salient features that make all the difference between a hopeful and a hopeless controversy. 336 For one thing, there is a certain intensity of emotion, interest, bias, or prejudice if you will, that can neither reason nor be reasoned with. 337 On the purely intellectual side, the disqualifying

circumstances are complexity and vagueness. 338 If a topic necessarily hauls in numerous other topics of difficulty, the essay may do something for it, but not the debate. 339 Worst of all is the presence of several large, ill-defined, or unsettled terms, of which there are still plenty in our department. 340 A not infrequent case is a combination of the several defects each perhaps in a small degree. 341 A tinge of predilection or party, a double or triple complication of doctrines, and one or two hazy terms, will make a debate that is pretty sure to end as it began. 342 Thus it is that a question, plausible to appearance, may contain within it capacities of misunderstanding, cross-purposes, and pointless issues, 343 sufficient to occupy the long night of Pandemonium, or beguile the journey to the nearest fixed star.

THE ART OF STUDY

Alexander Bain

15 Of hackneyed subjects, a foremost place may be assigned to the Art of Study. 2 Allied to the theory and practice of Education generally, it has still a field of its own, although not very precisely marked out. 3 It relates more to self-education than to instruction under masters; it supposes the voluntary choice of the individual rather than the constraint of an outward discipline. 4 Consequently, the time for its application is when the pupil is emancipated from the prescription and control of the scholastic curriculum.

5 There is another idea closely associated with our notion of study namely, learning from books. 6 We may stretch the word, without culpable licence, to comprise the observation of facts of all kinds, but it more naturally suggests the resort to book lore for the knowledge that we are in quest of. 7 There is a considerable propriety in restricting it to this meaning; or, at all events, in treating the art of becoming wise through reading, as different from the arts of observing facts at first hand. 8 In short, study should not be made co-extensive with knowledge getting, but with book learning. 9 In thus narrowing the field, we have the obvious

advantage of cultivating it more carefully, and the unobvious, but very real, advantage of dealing with one homogeneous subject.

10 In the current phrase, "studying under some one," there is a more express reference to being taught by a master, as in listening to lectures. 11 There is, however, the implication that the learner is applying own mind to the special field, and, at the same time, is not neglecting the other sources of knowledge, such as books. 12 The master is looked upon rather as a guide to enquiry, than as the sole fountain of the information sought. 13 Thus, then, the mental exercise that we now call "study" began when books began; when knowledge was reduced to language and laid out systematically in verbal compositions. 14 A certain form of it existed in the days when language was as yet oral merely; 15 when there might be long compositions existing only in the memory of experts, and communicable by speech alone. 16 But study then was a very simple affair: it would consist mainly in attentive listening to recitation, so as to store up in the memory what was thus communicated. 17 The art, if any, would attach equally to the reciter and to the listener; the duty of the one would be to accommodate own lessons in time, quantity, and mode of delivery to the retentive capacity of the other; 18 who, in own turn, would be required to con and recapitulate what you had been told, until you made it your own, whatever it might be worth.

BOOK STUDY AMONG THE ANCIENTS

19 Even when books came into existence, an art of study would be at first very simple. 20 The whole extent of book literature among the Jews before Christ would be soon read; and, when once read, there was nothing left but to re-read it in whole or in part, with a view of committal to memory, whether for meditative reflection, or for awakening the emotions. 21 We see, in the Psalms of David, the emphasis attached to mental dwelling on the particulars of the

Mosaic Law, as the nourishment of the feelings of devotion.

22 The Greek Literature about 350 B.C., when Aristotle and Demosthenes had reached manhood-- being then 34--, had attained a considerable mass; as one may see at a glance from Jebb's chronology attached to own Primer. 23 There was a splendid poetical library, including all the great tragedians, with the older and the middle Comedy. 24 There were the three great historians-- Herodotus, Thucydides, and Xenophon; and the orators--- Lysias, Isocrates, and Isaeus; there were the precursors of Socrates in Philosophy; and, finally, the Platonic Dialogues. 25 To overtake all these would employ several years of learned leisure; and to imbibe their substance would be a rich and varied culture, especially of the poetic and rhetorical kind. 26 To make the most of the field, a judicious procedure would be very helpful; there was evident scope for an art of study. 27 The fertile intellect of the Greeks produced the first systematic guides to high culture; the Rhetorical art for Oratory and Poetry, the Logical art for Reasoning, and the Eristic art for Disputation. 28 There was nothing precisely corresponding to an Art of Study, but there were examples of the self-culture of celebrated people. 29 The most notorious of these is Demosthenes; of whom we know that, while he took special lessons in the art of oratory, he also bestowed extraordinary pains upon the general cultivation of his intellectual powers. 30 His application to Thucydides in particular is recounted in terms of obvious mythical exaggeration; 31 showing, nevertheless, his idea of fixing upon a special book with a view to extracting from it every particle of intellectual nourishment that it could yield: in which we have an example of the art of study as I have defined it. 32 Then, it is said that, in his anxiety to master his author, he copied the entire work eight times, with his own hand, and had it by heart verbatim, so as to be able to re-write it when the manuscripts were accidentally destroyed.

33 We do not possess from the genius of Aristotle-- the originator or improver of so many practical

departments-- an Art of Study. The omission was not supplied by any other Greek writer known to us. 34 The oratorical art was a prominent part of education both in Greece and in Rome; and was discussed by many authors-- notably by Cicero himself; but the exhaustive treatment is found in Quintilian. 35 The very wide scope of the "Institutes of Oratory" comprises a chapter upon the orator's reading, in which the author reviews the principal Greek and Roman classics from Homer to Seneca, with remarks upon the value of each for the mental cultivation of the oratorical pupil. 36 Something of this sort might be legitimately included in the art of study, but might also be withheld, as being provided in the critical estimates already formed respecting all writers of note.

MODERN GUIDES TO STUDY

37 After Ouintilian, it is little use to search for an art of study, either among the later Latin classics, or among the mediaeval authors generally. 38 I proceed at once to remark upon the well-known essay of Bacon, which shows his characteristic subtlety, judiciousness, and weight; yet is too short for practical guidance. 39 He hits the point, as I conceive it, when he identifies study with reading, and brings in, but only by way of contrast and complement, conference or conversation and composition. 40 He endeavours to indicate the worth of book learning, as an essential addition to the actual practice of business, and the experience of life. 41 He marks a difference between books that we are merely to dip into-- books to be tasted-- and such as are to be mastered; without, however, stating examples. 42 He ventures also to settle the respective kinds of culture assignable to different departments of knowledge-- history, poetry, mathematics, natural philosophy, moral philosophy, logic and rhetoric; 43 a very useful attempt in its own way, and one that may well enough enter into a comprehensive art of study, if not provided for in the still wider theory of Education at large.

44 Bacon's illustrious friend, Hobbes, did not write on studies, but made a notable remark bearing on one topic connected with the art,-- 45 namely, that if he had read as much as other people, he should have remained still as ignorant as other people. 46 This must not be interpreted too literally. Hobbes was really a great reader of the ancients, and must have studied with care some of the philosophers immediately preceding himself. 47 Still, it indicates an important point for discussion in the art of study, in which great people have gone to opposite extremes-- I mean in reference to the amount of attention to be given to previous writers, in taking up new ground.

48 To come down to another great name, we have Milton's ideal of Education, given in his short Tractate. 49 Here, with many protestations of knowing things, rather than words, we find an enormous prescription of book reading, including, in fact, every known author on every one of a wide circle of subjects. 50 This was characteristic of the man: he was a voracious reader himself, and an example to show, in opposition to Hobbes, that original genius is not necessarily quenched by great or even excessive erudition. 51 As bearing on the art of study, especially for striplings under twenty, Milton's scheme is open to two criticisms: 52 first, that the amount of reading on the whole is too great; second, that in subjects handled by several authors of repute, one should have been selected as the leading text-book and got up thoroughly; 53 the others being taken in due time as enlarging or correcting the knowledge thus laid in. Think of a child learning Rhetoric upon six authors taken together!

LOCKE'S CONDUCT OF THE UNDERSTANDING

54 The transition from Milton to Locke is the inverse of that from Hobbes to Milton. Locke was also a man of few books. 55 If he had been sent to school under Milton, as he might have been, he would have very soon thrown up the learned drudgery prescribed for him, and would have bolted.

56 The practical outcome of Locke's enquiries respecting the human faculties is to be found in the little treatise named-- "The Conduct of the Understanding". 57 It is an earnest appeal in favour of devotion to the attainment of truth, and an exposure of all the various sources of error, moral and intellectual; more especially prejudices and bias. 58 There are not, however, many references to book study; and such as we find are chiefly directed to the one aim of painful and labourious examination, 59 first, of an author's meaning, and next of the goodness of own arguments. Two or three sentences will give the clue.

60 "Those who have read of everything, are thought to understand everything too; but it is not always so. 61 Reading furnishes the mind only with materials of knowledge; it is thinking makes what we read ours. 62 We are of the ruminating kind, and it is not enough to cram ourselves with a great deal of collections, unless we chew them over again, they will not give us strength and nourishment." 63 Farther: "Books and reading are looked upon to be the great helps of the understanding, and instruments of knowledge, as it must be allowed that they are; 64 and yet I beg leave to question whether these do not prove a hindrance to many, and keep several bookish people from attaining to solid and true knowledge". 65 Here, again, is his stern way of dealing with any author:-- "To fix in the mind the clear and distinct idea of the question stripped of words; 66 and so likewise, in the train of argumentation, to take up the authors' ideas, neglecting their words, observing how they connect or separate those in the question." Of this last, more afterwards.

WATT'S IMPROVEMENT OF THE MIND

67 A disciple of Locke, and a man of considerable and various powers, the non-conformist divine Isaac Watts, produced perhaps the first considerable didactic treatise on Study. 68 I refer, of course, to his well-known work entitled "The

Improvement of the Mind"; on which, he tells us, he was occupied at intervals for twenty years. 69 It has two Parts: one on the acquisition of knowledge; the other on Communication or leaching. 70 The scheme is a very wide one. Observation, Reading, attending Lectures, Conversation,-- are all included. 71 To the word "Study," Watts attaches a special meaning, namely Meditation and Reflection, together with the control or regulation of all the exercises of the mind. 72 I doubt if this meaning is well supported by usage. At all events it is not the signification that I propose to attach to the term. 73 Observation is an art in itself: so is Conversation, whether amicable or contentious. 74 The proportions that these exercises should bear to reading, would fairly claim a place in the complete Art of Study.

75 Watts has two short chapters on Books and Reading, containing sensible remarks. 76 He urges the importance of thorough mastery of select authors; but assumes a power of discriminating good and bad beyond the reach of a learner, and does not show how it is to be attained. 77 He is very much concerned all through as to the moral tone and religious orthodoxy of the books read, he also reproves hasty and ill-natured judgments upon the authors.

78 Watts's Essay is so pithily written, and so full of sense and propriety, that it long maintained a high position in our literature; he tells us, that it had become a text-book in the University. 79 I do not know of any better work on the same plan. 80 A "Student's Guide," by an American named Todd, was in vogue with us, some time ago; but anyone looking at its contents, will not be sorry that it is now forgotten. 81 It would not, however, be correct to say that the subject has died out. 82 If there have not been many express didactic treatises of late, there has been an innumerable host of small dissertations, 83 in the form of addresses, speeches, incidental discussions, leading articles, sermons-- all intended to guide both young and old in the path of useful study. 84 What to read, when to read, and how to read,-- have been themes of many an

essay, texts of many a discourse. 85 According as Education at large has been more and more discussed, the particular province of self-education, as here marked out, has had an ample share of attention from more or less qualified advisers.

86 What we have got before us, then, is, first, to define our ground, and then to appropriate and value the accumulated fruits of the labour expended on it. 87 I have already indicated how I would narrow the subject of Study, so as to occupy a field apart, and not jumble together matters that follow distinct laws. 88 The theory of Education in general is the theory of good Teaching: that is a field by itself, although many things in it are applicable also to self-education. 89 To estimate the values of different acquisitions--Science, Language, and the rest, is good for all modes of culture. 90 The laws of the understanding in general, and of the memory in particular, must be taken into account under every mode of acquiring knowledge. 91 Yet the alteration of circumstances, when a pupil is carving out own course, and working under own free-will, leads to new and distinct rules of procedure. 92 Also, that part of self-education consisting in the application to books is distinct from the other forms of mental cultivation, namely, conversing, disputing, original composition, and tutorial aid. 93 Each of these has its own rules or methods, which I do not mean to notice except by brief allusion.

94 In connection with the Plan of study, it is material to ask what the individual is studying for. Each profession, each accomplishment, has its own course of education. 95 If book reading is an essential part, then the choice of books must follow the line of the special pursuit. This is obvious; but does not do away with the consideration of the best modes of studying whatever books are suitable for the end. 96 One person has to read in Chemistry, another in Law, another in Divinity, and so on. For each and all of these, there is a profitable and an unprofitable mode of working, and the speciality of the matter is unessential.

DIFFERENT ENDS OF STUDY

97 The more important differences of subject, involving differences of method, are seen in such contrasted departments as science and language, thought and style, reality and poetry, generality and particularity. 98 In applying the mind to these various branches, and in using books as the medium of acquisition, there are considerable differences in the mode of procedure. 99 The study of a book of science is not on the same plan as the study of a history or a poem. 100 yet even in these last, there are many circumstances in common, arising out of the constitution of our faculties and the nature of a verbal medium of communication of thought.

101 An art of study in general should not presume to follow out in minute detail the education of the several professions. 102 There should still be, for example, a distinct view of the training special in an orator, on which the ancients bestowed so much pains; 103 there being no corresponding course hitherto chalked out for a Philosopher as such, or even for a Poet.

104 Next, there is an important distinction between studies for a professional walk, and the studies of a human's leisure, with a view to gratifying a special taste, 105 or for the higher object of independent thinking on all the higher questions belonging to a citizen and a person. 106 Both positions has its peculiarities; and an art of study should be catholic enough to embrace them. 107 To have the best part of the day for study, and the rest for recreation and refreshment, is one thing: and to study in by-hours, in snatches of time, and in holidays is quite another thing. 108 In the latter case, the choice of subjects, and the extent of them, must be considerably different; 109 while the consideration of the best modes of economising time and strength, and of harmonising one's life as a whole, is more pressing and more arduous. 110 But, when the course is chalked out, the details of study must conform to the general conditions of all acquirements in knowledge

through the instrumentality of books.

111 One, and only one, more preliminary clearing. When an instructor proceeds, as Milton in his school, or as James Mill with his son, by prescribing to each pupil a mass of books to be read, with more or less of examination as to their contents; 112 in such a case, education from without has passed into study in our narrow sense; and the procedure for one situation is applicable to both. 113 The two cases are equally in contrast to educating by the direct instruction of the teacher. 114 In so far, however, as any teacher requires book study to co-operate with own addresses, to that extent do the methods laid down for private study come into play.

115 Under every view, it is a momentous fact, that the person of modern times has become a book-reading animal. 116 The acquisition of knowledge and the cultivation of the intellectual powers of the mind, form only a small part of the use of books; although the part more properly named Study. 117 The moral tendencies are controlled; the emotions regulated; sympathy with humankind, or the opposite, generated; pleasurable excitement afforded. 118 These other uses may be provided apart, as in our literature of amusement, or they may be given in combination with the element of knowledge, 119 in which case they are apt to be a disturbing force, rendering uncertain our calculations as to the efficacy of particular modes of study.

120 The practical problem of Study is not to be approached by any high ‘priori’ road; in other words, by setting out from abstract principles as to the nature of the mind's receptivity and the operation of book-reading upon that receptivity. 121 A humbler line of approach will be more likely to succeed.

122 There exist a number of received maxims on study, the result of many people’s experience and wisdom. 123 Our endeavour will be to collect these, arrange them in a methodical plan, so that they may give mutual aid, and supply each other's defects. 124 We shall go a little farther, and criticise them according to the best

available lights; and, when too vague or sweeping, supply needful qualifications.

125 The Choice of Books, in the first instance, depends on the merits attributed to them severally by persons most conversant with the special department. 126 In some degree, too, this choice is controlled by the consideration of the best modes of study, as will soon be apparent.

A TEXT-BOOK-IN-CHIEF

127 Our first maxim is-- "Select a Text-book-in-chief". The meaning is, that when a large subject is to be overtaken by book study alone, some one work should be chosen to apply to, in the first instance, which work should be conned and mastered before any other is taken up. 128 There being, in most subjects, a variety of good books, the thorough student will not be satisfied in the long run without consulting several, and perhaps making a study of them all; 129 yet, it is unwise to distract the attention with more than one, while the elements are to be learnt.

130 In Geometry, the pupil begins upon Euclid, or some other compendium, and is not allowed to deviate from the single line of own author. 131 If you are once thoroughly at home on the main ideas and the leading propositions of Geometry, you are safe in dipping into other manuals, 132 in comparing the differences of treatment, and in widening your knowledge by additional theorems, and by various modes of demonstration.

133 In principle, the maxim is generally allowed. Nevertheless, it is often departed from in practice. This happens in several ways.

KEEPING TO A SINGLE LINE OF THOUGHT

134 One way is exemplified in Milton's Tractate, already referred to. His method of teaching any subject would appear to have been to take, the received authors, and to read them one after another, probably according to date; 135 the reading pace, and degree of concentration, being apparently equal all through. His six authors

on Rhetoric were-- Plato (select Dialogues, of course), Aristotle, Phalereus, Cicero, Hermogenes, Longinus. 136 To read their several treatises through in the order named, with equal attention, would undoubtedly leave in the mind a good many thoughts on Rhetoric, but in a somewhat chaotic state. 137 Much better would it have been to have adopted a Text-book-in-chief, the choice lying between Aristotle and Ouintilian-- who comes in at a prior stage of the Miltonic curriculum. 138 The book so chosen would be read, and re-read; or rather each chapter would be gone over several times, with appropriate testing exercises and examinations. 139 The other works might then be overtaken and compared with the principal text-book; 140 the judgment of the pupil being so far matured, as to see what in them was already superseded, and what might be adopted as additions to own already acquired stock of ideas.

141 Milton's views of education embraced the useful to a remarkable degree; he was no pamperer of imagination and the ornamental. 142 His list of subjects might be said to be utility run wild:-- comprising the chief parts of Mathematics, together with Engineering, Navigation, Architecture, and Fortification; 143 Natural Philosophy; Natural History; Anatomy, and Practice of Physic; Ethics, Politics, Economics, Jurisprudence, Theology; a full course of the Orators and Poets; Logic, Rhetoric, and Poetics. 144 He tumbles out a whole library of reading: but only in Ethics, does he indicate a leading or preferential work; 145 the half-dozen of classical books on the subject are to be perused, "under the determinate sentence" of the scripture authorities. 146 With all this voracity for the useful, Milton had no conception of scientific form, or method; 147 and indeed, few of the subjects had as yet passed the stage of desultory treatment; so that the idea of casting the knowledge into some one form, under the guidance of a chosen author, would never occur to him.

148 Better things might have been expected of James Mill, in

conducting the education of his son. 149 Yet we find his plan to have been to require an even and exhaustive perusal of nearly every book on nearly every subject, without singling out any one to impart the best known form in each case. 150 The disadvantage of the process would be that, at first, all the writers were regarded as profitable alike. 151 Nevertheless, in the special subjects that he knew himself, he gave his own instructions as the leading text, and his pupil's knowledge took form according to these. 152 In some cases, accident gave a text-in-chief, as when young Mill at ten years of age, studied Thomson's Chemistry, without the distraction of any other work. 153 If there had been half-a-dozen Chemical manuals in existence, he would probably have read them all, and fared much worse. 154 It happens, however, that, in the more exact sciences, there is a greater sameness in the leading ideas, than in Politics, Morals, or the Human Mind; and the evil of distraction is so much smaller.

155 Undoubtedly, the best of all ways of learning anything is to have a competent master to dole out a fixed quantity every day, just sufficient to be taken in, and no more; 156 the pupils to apply themselves to the matter so imparted, and to do nothing else. 157 The singleness of aim is favourable to the greatest rapidity of acquirement; and any defects are to be left out of account, until one thread of ideas is firmly set in the mind. 158 Not infrequently, however, and not improperly, the teacher has a text-book in aid of his oral instructions. 159 To make this a help, and not a hindrance, demands the greatest delicacy; the sole consideration being that the pupil must be kept in one single line of thought, and never be required to comprehend, on the same point, conflicting or varying statements.

160 Even the foot-notes to a work may have to be disregarded, in the first instance. They may act like a second author, and keep up an irritating friction. 161 There is, doubtless, a consummate power of annotation that anticipates difficulties, and clears away haze, without distracting the mind. 162 There is also an art of bringing out

relief by an accompaniment, like the two images of the stereoscope. 163 This is most likely to arise through a living teacher or commentator, who, by own tones and emphasis, as well as by own very guarded and reserved additions, can make the meaning of the author take shape and fullness.

164 As the chief text-book is chosen, among other reasons, for its method and system, any defects on this head may be very suitably supplied, during the reader's progress, by notes or otherwise. 165 When the end is clearly kept in view, we shall not go wrong as to the means: the spirit will remedy an undue bias to the letter.

166 The subjects that depend for their full comprehension upon a certain method and order of details, are numerous, and include the most important branches of human culture. 167 The Sciences, in mass, are avowedly of this character: even such departments as Theology, Ethics, Rhetoric, and Criticism have their definite form; 168 and, until the mind of the student is fully impressed with this, all the particulars are vague and chaotic, and comparatively useless for practical application. 169 So, any subject cast in a polemic form must be received and held in the connection thereby given to it. 170 If the arguments pro and con fall out of their places in the mind of the reader, their force is missed or misconceived.

171 History is pre-eminently a subject for method, and, therefore, involves some such plan as is here recommended. 172 Every narrative read otherwise than for mere amusement, as we read a novel, should leave in the mind-- 173 (1) the Chronological sequence (more or less detailed); and (2) the Causal sequence, that is, the influences at work in bringing about the events. 174 These are best gained by application to a single work in the first place; other works being resorted to in due time.

175 Of the non-methodical subjects, forming an illustrative contrast, mention may be made of purely didactic treatises, where the precepts are each valuable for itself, and by itself: 176 such as, until very recently, the works on Agriculture, and even on

Medicine. 177 A book of Domestic Receipts, consulted by index, is not a work for study.

178 Poems and fictitious narrations will naturally be regarded as of the un-methodical class. 179 If there are exceptions, they consist of long poems-- Epics and Dramas-- whose plan is highly artistic, and must be felt in order to the full effect. 180 Probably, however, this is the merit that the generality of readers are content to miss, especially if greater strain of attention is needed to discover it. 181 Readers bent on enjoyment dwell on the passing page, and are not inclined to carry with them what has gone before, in order to understand what is to follow.

REPUDIATION OF METHOD BY MEN OF REPUTE

182 Very intelligent and superior people have wholly repudiated the notion of study by method. 183 We must not lay too much stress upon these disclaimers, seeing that they are usually cited from those in advanced years, or people whose day of methodical education is passed. 184 When Johnson said-- "A man ought to read just as inclination leads him," he was not thinking of beginners, for whom he would probably have dictated a different course. 185 Still, it is a prevailing tendency of many minds, to read all books equally, provided the interest or enjoyment of them is equal. 186 Macaulay, Sir William Hamilton, De Quincey, as well as Johnson, and a numerous host besides, were book-gluttons, books in breeches; they imbibed information copiously, and also retained it, but as a matter of chance. 187 The enjoyment of their life was to read; whereas, to master thoroughly a considerable field of knowledge, can never be all enjoyment. 188 Gibbon was a book devourer, but he had a plan; he was organising a vast work of composition. 189 Macaulay, also, showed himself capable of realising a scheme of composition; both his History and his Speeches have the stamp of method, even to the pitch of being valuable as models. 190 Hamilton and De Quincey, each in his way, could form high ideals of work, and in part execute them; but their productiveness suffered from too

much bookish intoxication. 191 While readers generally mix the motive of instruction with stimulation, the class that seek instruction solely is but small; the other extreme is frequent enough.

DIFFICULTY IN CHOOSING A FIRST TEXT-BOOK

192 In many subjects, the difficulties of fixing upon the proper Text-book are not inconsiderable. 193 The mere reputation of a book may be great, and well-founded; and yet the merits may not be of the kind that fits it for the commencing student. 194 Such conditions as the following must be taken into account. The Form or Method should be of a high order: this we shall have occasion to illustrate under the next head. 195 It should be abreast: of the time, on its own subject. It should be moderately full, without being necessarily exhaustive in detail. It is on this point that the cheap primers of the present day are mainly defective. 196 They state general ideas, and lay down outlines; but they do not provide sufficiently expanded illustration to stamp these on the mind of the learner. 197 A shilling primer is really a more advanced book than one on a triple scale, that should embrace the same compass of leading ideas. 198 As a farther condition, the work chosen should not have so much of individuality as to fail in the character of representing the prevailing views. 199 The greatest authors often err on this point; and, while a work of genius is not to be neglected, it may, for this reason, have to take the second place in the order of study.

200 Newton's ‘Principia’ could never be a work suited for an early stage of mathematical study. 201 Lyell's Geology has been a landmark in the history of the subject; but it is not cast in the form for a beginner in Geology. 202 It is, in its whole plan, argumentative; setting up and defending a special thesis in Geology; the facts being arrayed with that view. 203 Many other great works have assumed a like form; such are Malthus on Population, Grove's Correlation of Physical Forces, Darwin's Origin

of Species. 204 Even expressly didactic works are often composed more to bring forward a peculiar view, than from the desire to develop a subject in its due proportions. 205 Locke's Essay on the Understanding does not propose to give a methodical and exhaustive handling of the Powers of the Mind, or even of the Intellect. That was reserved for Reid.

206 The question as between old writers and new, would receive an easy solution upon such grounds as the foregoing, were it not for the sentiment of veneration for the old, because they are old. 207 If an ancient writer retains a place by virtue of surpassing merits, as against all subsequent writers, own case is quite clear. 208 In the nature of things, this must be rare: if there be an example, it is Euclid; yet his position is held only through the mutual jealousy of his modern rivals. 209 The only motive for commencing a study upon a very old writer is a desire to work out a subject historically; which, in some instances may be allowed, but not very often.

210 In Politics, Ethics, and Rhetoric, the plan might have its advantages; but, with this imperative condition, that we shall follow out the development in the modern works. 211 In proportion as a subject assumes a scientific shape, it must carefully define its terms, marshal its propositions in proper dependence, and offer strict proof of all matters of fact; 212 now, in these respects, every known branch of knowledge has improved with the lapse of ages; so that the more recent works are necessarily the best for entering upon the study. 213 A historical sequence may be proper to be observed; but that should be backward and not forward. 214 The earlier stages of some subjects are absolutely worthless; as, for example, Physics, Chemistry, and most of Biology, 215 in other subjects, as Politics and Ethics, the tentatives of such men as Plato and Aristotle have an undying value; nevertheless, the student should not begin, but end, with them.

216 There is an extreme form of putting our present doctrine that runs it into paradox: namely, the one-book-and-no-more maxim. 217

Scarcely any book in existence is so all-sufficient for its purpose that a student is better occupied in re-reading it for the tenth time, than in reading some others once. 218 Even the merits of the one book are not fully known unless we compare it with others; 219 nor have we grasped any subject unless we are able to see it stated in various forms, without being distracted or confused. 220 It is not a high knowledge of horsemanship that can be gained by the most thorough acquaintance with one horse.

NO WORK ENTIRELY SELF-SUFFICIENT

221 Any truth that there is in the paradox of excluding all books but one from perusal, belongs to it as a form of the maxim we have now been considering. 222 There is not in existence a work corresponding to the notion of absolute self-sufficiency. 223 Suppose we were to go over the chef-d'oeuvres of human genius, we should not find one in the position of entire independence of all others. 224 Take, for example, the poems of Homer; the Republic and a few other of Plato's pre-eminent Dialogues; the great speeches of Demosthenes; the Ethics and Politics of Aristotle; 225 the poems of Dante; Shakespeare, as a whole; Bacon's Novum Organum; Newton's Principia; Locke on the Understanding; the Méchanique Céleste of Laplace. 226 No one of all these could produce its effect on the mind without referring to other works, previous, contemporary, or following. 227 The remark is not confined to works of elucidation and comment merely-- as the contemporary history of Greece, or the speeches of Demosthenes-- but extends to other compositions, of the very same tenor, by different, although inferior, writers. 228 Shakespeare himself is made much more profitable by a perusal of the other Elizabethans, and by a comparison with dramatic models before and after him.

229 The nearest approach to a perfectly all-sufficing book is seen in scientific compilations by a conjunction of highly accomplished editors. 230 A new

edition of Quain's Anatomy, revised and brought up to date by the best anatomists, would, for the moment, probably be fully adequate to the wants of the student, and dispense with all other references whatsoever. 231 Not that even then, it would be desirable to abstain from ever opening a different compendium; although undoubtedly there would be the very minimum of necessity for doing so. 232 Nevertheless, literature presents few analogous instances. One of the great works of an original genius, like Aristotle, might, by profuse annotation, be made nearly sufficing; 233 but this is another way of reading by quotation a plurality of writers; and it would be better still to peruse some of these in full, there being no need for studying them with the degree of intensity bestowed on a main work.

LOCKE'S TREATMENT OF THE BIBLE

234 The example, by pre-eminence, of one self-sufficing work is the Bible. Being the sole and ultimate authority of Christian doctrine, it holds a position entirely apart; 235 and, among Protestants at least, there is a becoming jealousy of allowing any extraneous writing to overbear its contents. 236 Yet we are not to infer, as many have done practically, that no other work needs to be read in company with it. 237 Granting that its genuine doctrines have been overlaid by subsequent accretions, the way to get clear of these is not to neglect the entire body of fathers, commentators, and theologians, and to give the whole attention to the scriptural text. 238 Locke himself set an example of this attempt. He proposed, in his "Reasonableness of Christianity," to ascertain the exact meaning of the New Testament, 239 by casting aside all the glosses of commentators and divines, and applying his own unassisted judgment to spell out its teachings. 240 He did not disdain to use the lights of extraneous history, and the traditions of the heathen world; he only refused to be bound by any of the artificial creeds and systems devised in later ages to embody

the doctrines supposed to be found in the Bible.

241 The fallacy of his position obviously was, that he could not strip himself of his education and acquired notions, the result of the teaching of the orthodox church. 242 He seemed unconscious of the necessity of trying to make allowance for his unavoidable prepossessions. 243 In consequence, he simply fell into an old groove of received doctrines; and these he handled under the set purpose of simplifying the fundamentals of Christianity to the utmost. 244 Such purpose was not the result of his Bible study, but of his wish to overcome the political difficulties of the time. 245 He found, by keeping close to the Gospels and by making proper selections from the Epistles, that the belief in Christ as the Messiah could be shown to be the central fact of the Christian faith; 246 that the other main doctrines followed out of this by a process of reasoning; and that, as all minds might not perform the process alike, these doctrines could not be essential to the acceptance of Christianity. 247 He got out of the difficulty of framing a creed, as many others have done, by simply using Scripture language, without subjecting it to any very strict definition; 248 certainly without the operation of stripping the meaning of its words, to see what it amounted to. 249 That his short and easy method was not very successful, the history of the Deistical controversy sufficiently proves. 250 The end in view would, in our time, be sought by an opposite course. 251 Instead of disregarding commentators, and the successions of creed embodiments, a scholar of the present day would ascend through these to the original, 252 and find out its meaning, after making allowance for all the tendencies that operated to give a bias to that meaning. 253 As to putting us in the position of listening to the Bible authors at first hand, we should trust more to the erudition of a Pusey or an Ewald, than to the unassisted judgment of a Locke.

254 "What constitutes the study of a book?" Mere perusal at the average reading pace is not the way to imbibe the contents of any

work of importance, especially if the subject is new and difficult.

255 There are various methods in use among authoritative guides. To revert to the Demosthenic traditions: we find two modes indicated-- namely, repeated copying, and committing to memory verbatim. 256 A third is, making abstracts in writing. A fourth may be designated the Lockian method. Let us consider the respective merits of the four.

STUDY BY LITERAL COPYING

257 Of copying a book literally through, there is this to be said, that it engages the attention upon every word, until the act of writing serves to impress the memory. 258 But there are very important qualifications to be assigned in judging of the worth of the exercise. Observe what is the main design of the copyist. It is to produce a replica of an original upon paper. 259 You cannot do this without a certain amount of attention to the original; enough at least to enable you to put down the exact words in the copy; and, by such attention, you are so far impressed with the matter, that a certain portion may remain in the memory. 260 If, however, instead of the paper, you could write directly on the brain, you would be aiming straight at your object. 261 Now, experience shows that the making of a copy of any document is compatible with a very small amount of attention to the purport. 262 The extreme case is the copying clerk. You can literally reproduce an original, with entire forgetfulness of what it is about. 263 If your eye takes a faithful note of the sequence of words, you may entirely neglect the meaning. In point of fact, you constantly does so. 264 You remembers nobody's secrets; and you cannot be counted on to check blunders that make nonsense of your text. 265 Probably no one could go on copying for eight hours a day unless the strain of attention to the originals were at a minimum.

266 I conceive, therefore, that copying habits arising from a certain amount of experience at the vocation, would be utterly fatal to the employment of the exercise as

a means of study. 267 It may be valuable to such as have seldom used their pen except in original composition. 268 Very probably, in school lessons, to write an exercise two or three times may be a help to the usual routine of staying off the book. 269 I have heard experienced teachers testify to the good effects of the practice. Yet very little would turn the attention the wrong way. 270 Even the requirement of neatness on the part of the master, or the pupil's own liking for it, would abate the desired impression. 271 The multiplied copying set as punishment might stamp a thing on the memory through disgust; it might also engender the mechanical routine of the copyist. 272 In short, to sit down and copy a long work is about the last thing that I should dream of, as a means of study. 273 To copy Thucydides eight times, as the tradition respecting Demosthenes goes, would be about the same as copying Gibbon three times: and who would undertake that?

COMMITTING TO MEMORY WORD FOR WORD

274 Committing to memory verbatim, or nearly so. This too belongs to the same tradition regarding Demosthenes, and is probably as inaccurate as the other. 275 Certainly the eight copyings would not suffice for having the whole by heart. 276 Excepting a professional rhapsodist, or some one gifted with extraordinary powers of memory that would hardly be compatible with a great understanding, nobody would think of committing Thucydides to memory. 277 That Demosthenes should be a perfect master both of the narrated facts, and of the sagacious theorisings of Thucydides in those facts, we may take for granted. 278 And, farther, the orations delivered by opposing speakers in the great critical debates, might very well have been committed verbatim by a young orator; many of them are masterpieces of oratory in every point of view. 279 But the reason for getting them by heart does not apply to the general narrative. 280

Even to imbibe the best qualities of the style of Thucydides would not require whole pages to be learnt verbatim; a much better way would readily occur to any intelligent person.

281 In fact, there is no case where it is profitable to load the memory with a whole book, or with large portions of a book. 282 There are many small portions of every leading work that might be committed with advantage. Principal propositions ought to be retained to the letter. 283 Passages, here and there, remarkable for compact force, for argumentative power, or elegant diction, might be read and re-read till they clung to the memory; but this should be the consummation of a thorough and critical estimate of their merits. 284 To commit to memory without thinking of the meaning is a senseless act; and could not be ascribed to Demosthenes. 285 At the stage when the young student is forming a style, one is assisted by laying up ‘memoriter’ a number of passages of great authors; but it is never necessary to go beyond select paragraphs. 286 Detached sentences are valuable, and strain the memory least. Entire paragraphs have a farther value in impressing good paragraph connection; 287 but, to string a number of paragraphs together, or to learn whole chapters by memory, has nothing to recommend it in the way of mental culture.

288 There is a memory in extension that holds a long string of words and ideas together. Its value is to get readily at anything occurring in a certain train, as in a given book. It is the memory of easy reference. 289 There is also a memory of ‘intension’, that takes a strong grasp of brief expressions and thoughts, and brings them out for use, on the slightest relevancy. 290 The two modes interfere with each other's development; we cannot be great in both; 291 while, for original force, the second is worth the most: it extracts and resets gems to tesselate our future structures; it constitutes depth as against fluency.

292 To commit poetical passages to memory is a valuable contribution to our stock of material for emotional resuscitation in after years. 293 It also aids in adorning

our style, even although we may not aspire to compose in poetry. But the burden of holding the connection of a long poem should be eschewed. 294 Children can readily learn a short psalm or hymn, and can retain it in permanence; but to repeat the 119th psalm from the beginning is the mere tour-de-force of a strong natural memory, and a waste of power; 295 just as much as committing an entire book of the Aeneid or of Paradise Lost.

MAKING ABSTRACTS

296 Making Abstracts.-- This is the plan of studying that most advances our intelligent comprehension of any work of difficulty, and also impresses it on the memory in the best form. 297 But there are many ways of doing it; and beginners, from the very fact that they are beginners, are not competent to choose the best. 298 If a book has an obvious and methodical plan in itself, the reader can follow that plan, taking down the leading positions, 299 selecting some of the chief examples or illustrations, giving short headings of chapters and paragraphs, and thus making a synopsis, or full table of contents. All this is useful. 300 The memory is much better impressed through the exertion of picking, choosing, and condensing, than by copying verbatim; and the plan or evolution of the whole is more fully comprehended. 301 But, if a work does not easily lend itself to a methodical abstract, the task of the beginner is much harder.

302 To abstract the treatises of Aristotle was fitting employment for Hobbes. 303 The "Wealth of Nations" is not easy to abstract; but, at the present day, it would not be chosen as the Text-book-in-chief for Political Economy: as a third or fourth work to be perused at a reading pace, it would have its proper effect. 304 The best studious exercise upon it would be to mark the agreements and disagreements with the newer authority, the weak and strong points of the exposition, and the perennial force of a certain number of the propositions and examples. 305 Many parts could be skipped entirely as not even repaying

historical study. Yet, as the work of a great and original mind, its interest is perennial.

306 To go back once more to the example of Thucydides. Setting aside, from intrinsic improbability, both the traditions-- the copyings, and the committal to memory verbatim,-- we can easily see what Demosthenes could find in the work, and how he could make the most of it. 307 The narrative or story could be indelibly fixed in his memory by a few perusals, and, if need be, by a full chronology drawn up by his own hand. 308 The speeches could be committed in whole or in part, for their arguments and language; 309 and a minute study could be made of the turns of expression, as they seemed to be either meritorious or defective. 310 The young orator had already studied the more finished styles of Isocrates, Lysias, Isanis, and Plato, and could make comparisons between their forms and the peculiarities of Thucydides, which belonged to an earlier age. 311 This, however, was a discipline altogether apart, and had nothing to do with copying, committing, or abstracting. 312 It involved one exercise more or less allied to the last, namely, ‘making changes upon an author, according to ones best ideal at the time’: 313 changes, if possible, for the better, but perhaps not; still requiring, however, an effort of mind, and so far favourable to culture.

VARIOUS MODES OF ABSTRACTING

314 Every one's first attempts at abstracting must be very bad. There is no more opportune occasion for the assistance of a tutor or intelligent monitor, than to revise an abstract. 315 The weaknesses of a beginner are apparent at a glance; even better than by a viva-voce interrogation. 316 Useful abstracting comes at a late stage of study, when one or two subjects have been pretty well mastered. 317 It is then that the pupil can best overtake more advanced works on the subjects already commenced, or can enter upon an entirely new department, in the light of previous acquisitions.

318 Any work that deserves thorough study deserves the labour of making an abstract; without which, indeed, the study is not thorough. 319 It is quite possible to read so as to comprehend the drift of a book, and yet forget it entirely. The point for us to consider is-- Are we likely to want any portion of it afterwards? 320 If we can fix upon the parts most likely to be useful, we either copy or abstract these, or preserve a reference so as to turn them up when wanted. 321 In the case of a work, containing a mass of new and valuable materials, such as we wish to incorporate with our intellectual structure, we must act the part of the beginner in a new field, and make an abstract on the most approved plan: 322 that is, by such changes as shall at once preserve the author's ideas, and intersperse them with our own. 323 There is an ideal balance of two opposing tendencies: one to take down the writer too literally, which fails to impress the meaning; 324 the other to accommodate the writer too much to our own language and thinking, in which case, we shall remember more, but it will be remembering ourselves and not the writer. 325 You that can hit the just mean between these extremes is the perfect student.

326 There are easier modes of abstracting, such as serve many useful purposes, although not sufficient for the mastery of a leading Text-book, or even of a second or third in a new subject. 327 We may pencil on the margin, or underscore, all the leading propositions, and the typical examples. 328 In a well-composed scientific manual, the proceeding is too obvious to be impressive. 329 Very often, however, the main points are not given in the most methodical way, but have to be searched out by carefully scanning each paragraph. 330 This is an exercise that both instructs and impresses us; it is the kind of change that calls our faculties into play, and gives us a better hold of an author, without superseding the author.

331 A Table of Contents carefully examined is favourable to a comprehensive view of the whole; and, this attained, the details are remembered in the best possible

way, that is, by taking their place in the scheme. 332 Any other form of recollection is of the desultory kind.

LOCKE'S RECOMMENDATIONS

333 Let us next glance at Locke's method of reading, which is unique and original, like the man himself. 334 It is given with much iteration in his Conduct of the Understanding, but comes in substance to this:-- 335 We are to fix in the mind the author's ideas, stripped of his words; to distinguish between such ideas as are pertinent to the subject, and such as are not; 336 to keep the precise question steadily before our minds; to appreciate the bearing of the arguments; and, finally, to see what the question bottoms upon, or what are the fundamental verities or assumptions underneath.

337 All this is very thorough in its way; but, in the first place, it applies chiefly to argumentative works, and, in the second place, it is entirely beyond the powers of ordinary students. 338 Such an examination of an author as Locke contemplates is not seen many times in a generation. His own controversies give but indifferent examples of it; 339 several of Bentham's works and a few of John Mill's polemical articles also give an idea of thorough handling; 340 but it is not so properly a studious effort, as the consummated product of a highly logical discipline, and is within the reach of only a small elect number. 341 Locke would have been more intelligible, if, instead of telling us to strip an author's meaning of the words, he had impressed strongly the necessity of defining all leading terms; and of making sure that each was always used in the same meaning. 342 While, in order to veracious conclusions, it is necessary that every matter of fact should be truly given, it is equally necessary that the language should be free from ambiguity. 343 If an author uses the word "law," at one time as an enactment: by some authority, and at another time, as a sequence in the order of Nature, the author is sure to land us in fallacy and confusion, as Butler

did in explaining the Divine government. 344 The remedy is, not to perform the operation of separating the meaning entirely from the language, but to vary the language, so as to substitute terms that have no ambiguity. 345 "Law" is equivocal; "social enactment," and "order of Nature," are both unequivocal; and when one is chosen, and adhered to, the confusion is at an end.

346 The mere art of study is no preparation for such a task. It demands a very advanced condition of knowledge on the particular subject, as well as a logical habit of mind, however acquired; 347 and to include it in a practical essay on the Conduct of the Understanding is to overstep the limits of the subject.

348 As our present head represents the very pith and marrow of the art of study, we may dwell a little longer on the process of changing the form of an author, 349 whether by condensing, expanding, varying the expression, altering the order, selecting, and rejecting,-- or by any other known device. 350 Worst of all is change for the mere sake of change; it is simply better than literal copying. But, to rise above it, needs a sense of FORM already attained. 351 According as this sense is developed, the exercise of altering or amending is more and more profitable. 352 Consequently, there should be an express application of the mind to the attainment of form; and particular works pre-eminent for that quality should be sought out and read. 353 "Form" is doubtless a wide word, and comprises both the logical or pervading method of a work, and the expression or dress throughout. 354 Method by itself can be soonest acquired because it turns on a small number of points; 355 language is a multifarious acquirement, and can hardly be forced, although it will come eventually by due application.

EXAMPLE FROM PRACTICE OF MEDICINE

356 To show what is meant by learning Form, with a view to the more effectual study of subject-matter, I will take the example of a work on the Practice of Medicine; in which the idea is to describe

Diseases ‘seriatim’, with their treatment or cures. 357 At the present day, this subject possesses method or form: there is a systematic classification of diseased processes and diseases; 358 also, a regular plan of setting forth the specific marks of each disease, its diagnosis, and, finally, its remedies. 359 There are more and less perfect models of the methodical element; while there are differences among authors in the fullness of the detailed information. 360 There is, besides, a Logic of Medicine, representing the absolute form, in a kind of logical synopsis, by which it is more easily comprehended in the first instance: 361 not to mention the general body of the Logic of the Inductive Sciences, of which medicine is one. 362 Now, undoubtedly, the best work to begin with-- the Text-book-in-chief-- would be one where Form is in its highest perfection; the amount of matter being of less consequence.

363 In a subject of great complication, and vast detail, the student cannot too soon get possession of the best method or form of arrangement. 364 When a work of this character is before you, you are to read and re-read it, till the form becomes strongly apparent; 365 you are to compare one part with another, to see how the author adheres to your own pervading method; 366 you should, if possible, make a synopsis of the plan in itself, disentangling it from the applications, for greater clearness. 367 The scheme of a medical work, for example, comprises the Classification of Diseases, the parting off of Diseased Processes--- Fever, Inflammation,-- from Diseases properly so called; 368 the modes of defining Disease; the separation of defining marks, from predications, and so on: all involved in a strict Logic of Disease. 369 Armed with these logical or methodical preliminaries, the student next attacks one of the extended treatises on the Practice of Medicine. 370 You are now prepared to work the process of abstracting to the utmost advantage, both for clearness of understanding, and for impressing the memory. 371 As in such a vast

subject, no one author is deemed adequate to a full exposition, and as, moreover, a great portion of the information occurs, apart from systems, in detached memoirs or monographs,-- 372 the only mode of unifying and holding together the aggregate, is to reduce all the statements to a common form and order, by help of the pre-acquired plan. 373 The progress of study may amend the plan, as well as add to the particular information; but absolute perfection in the scheme is not so essential as strict adherence to it through all the details. 374 To work without a plan at all, is not merely to tax the memory beyond its powers, but probably also to misconceive and jumble the facts.

375 To enhance the illustration of the two main heads of the Art of Study, I will so far deviate from the idea of the essay, 376 as to take up a special branch of education, which, more than any other, has been reduced to form and rule, I mean the great accomplishment of Oratory, or the Art of Persuasion. 377 The practical Science of Rhetoric, cultivated both by ancients and by moderns, has especially occupied itself with directions for acquiring this great engine of influencing humankind. 378 It was emphatically averred by the ancient teachers of the Oratorical art, that it must be grounded on a wide basis of general information. 379 I do not here discuss the exact scope of this preparatory study, as my purpose is to narrow the illustration to what is special to the faculty of persuasion. 380 I must even omit all those points relating to delivery or elocution, on which so much depends; 381 and also the consideration of how to attain readiness or fluency in spoken address, except in so far as that follows from abundant oratorical resources. 382 We thus sink the difference between spoken oratory, and persuasion through the press.

383 Even as thus limited, oratory is still too wide for a pointed illustration: and, so, I propose farther to confine my references to the department of Political Oratory; 384 coupling with that, however, the Forensic branch-- which has much in common with the other, and has given birth to

some of our most splendid examples of the art of persuasion.

385 While declining to enter on the wide field of the general education of the orator, I may not improperly advert to the more immediate preparation for the political orator, by a familiar acquaintance with History and Political Philosophy, howsoever obtained. 386 Then, on the other hand, the course here to be chalked out assumes a considerable proficiency in language or expression. 387 The special education will incidentally improve both these accomplishments, but must not be relied on for creating them, or for causing a marked advance in either. 388 The effect to be looked for is rather to give them direction for the special end.

EXAMPLE FROM THE ART OF ORATORY

389 These things premised, the line of proceeding manifestly is to study the choicest examples of the oratorical art, according to the methods already laid down, with due adaptation to the peculiarities of the case.

390 Now, we have not, as in a Science, two or three systematic works, one of which is to be chosen as a chief, to be followed by a reference more or less to the others. 391 Our material is a long series of detached orations; from these we must make a selection at starting, 392 and such selection, which may comprise ten or twenty or more, will have to be treated with the intense single-minded devotion that we hitherto limited to a single work. 393 Repeated perusal, with a process of abstracting to be described presently, must be bestowed upon the chosen examples, before embarking, as will be necessary, upon the wide field of miscellaneous oratory.

394 No doubt, an oratorical education could be grounded in a general and equal study of the orators at large, taking the ancients either first or last, according to fancy. 395 Probably the greater number of students have fallen into this apparently obvious course. 396 Our present contention is, that it is better to make a

thorough study of a proper selection of the greatest speeches, together with the most persuasive unspoken compositions. 397 This, however, is not all. We are following the wisdom of the ancients, in insisting on the farther expedient of proceeding to the study of the great examples by the aid of an oratorical scheme.

398 At a very early stage of Oratory in Greece, its methods began to be studied, and, in the education of the orator, these methods were made to accompany the study of exemplary speeches. 399 The principles of Rhetoric at large, and of the Persuasive art in particular, have been elaborated by successive stages, and are now in a tolerable state of advancement. 400 The learner will choose the scheme that is judged best, and will endeavour to master it provisionally, before entering on the oratorical models; holding it open to amendment from time to time, as your education goes on. 401 The scheme and the examples mutually act and re-act: the better the scheme, the more rapidly will the examples fructify; and the scheme will, in its turn, profit by the mastery of the details.

NECESSITY OF AN ORATORICAL ANALYSIS

402 One great use of an oratorical analysis, as supplied by the teachers of Rhetoric, is to part off the different merits of a perfect oration; and to show which are to be extracted from the various exemplary orators. 403 One person excels in forcible arguments, another in the lucid array of facts; one is impressive and impassioned, another is quiet but circumspect. 404 Now, the benefit of studying on principle, instead of working at random, is, that we concentrate attention on each one's strong points, and disregard the rest. But it needs a preparatory analysis, in order to make the discrimination. 405 All that the uninstructed reader or hearer of a great oration knows is, that the oration is great: this may be enough for the persons to be moved; it is insufficient for an oratorical disciple.

406 In the hazardous task of pursuing the illustration by naming the examples of oratory most suitable to commence with, I shall pass over living people, and choose from the past orators of our own country. 407 Without discussing minutely the respective merits of individuals, I am safe in selecting, as in every way suitable for our purpose, Burke, Fox, Erskine, Canning, Brougham, and Macaulay. 408 Burke's Speeches on America; Fox on the Westminster Scrutiny; Erskine on Stockdale, and on Hardy, Tooke; Canning on the Slave Trade; Brougham, Lyndhurst, and Denman in the Queen's Trial; Macaulay on the Reform Bill,-- 409 would comprise, in a moderate compass, a considerable range of oratorical excellence. 410 I doubt if any member of the list would be more suitable for a beginning than Macaulay's Reform Speeches. 411 These are no mere displays of a brilliant imagination: they are known to have influenced thousands of minds otherwise averse to political change. 412 The reader finds in them an immense repository of historical facts as well as of doctrines; but facts and doctrines, by themselves, do not make oratory. 413 It is the use made of these, that gives us the instruction we are now in quest of. 414 In a first or second reading, however, matter and form equally captivate the mind. 415 It would be impossible, at that early stage, to make an abstract such as would separate the oratorical from the non-oratorical merits. 416 Only when, by help of our scheme, we have made a critical distinction between the two kinds of excellence, are we able to arrive at an approach to a pure oratorical lesson; and, for a long time, we shall fail to make the desired isolation. 417 We have to learn not to expect too much from any one speech: to pass over in Macaulay, what is more conspicuously shown, say in Fox, or in Erskine. 418 If our political and historical education has made some progress, the mere thoughts and facts do not detain us; their employment for the end of persuasion is what we have to take account of.

COMPREHENSIVE PRINCIPLE OF ORATORY

419 It is impossible here to indicate, except in a very general way, the successive steps of the operation. 420 The one summary consideration in the Rhetoric of Oratory, from which flows the entire array of details, is the regard to the dispositions and state of mind of the audience; 421 the presenting of topics and considerations that chime in with these dispositions, and the avoiding of everything that would conflict with them. 422 To grasp this comprehensive view, and to follow it out in some of the chief circumstantials of persuasive address-- 423 the leading forms of argument, and the appeals to the more prominent feelings,-- would soon provide a touchstone to a great oration, and lead us to distinguish the materials of oratory from the use made of them.

424 Take the circumstance of negative tact; by which is meant the careful avoidance of whatever might grate on the minds of those addressed. 425 Forensic oratory in general, and the oratory of Parliamentary leaders in particular, will show this in perfection; and, for a first study of it, there is probably nothing to surpass the Erskine Speeches above cited. 426 It could, however, be found in Macaulay; although in a different proportion to the other merits.

427 The Macaulay Speeches have the abundance of matter, and the powers of style, that minister to oratory, although not constituting its distinctive feature. 428 In these speeches, we may note how he guages the minds of the men of rank and property, in and out of Parliament, who constituted the opposition to Reform; 429 how tenderly he deals with their prejudices and class interests; how he shapes and adduces his arguments so as to gain those very feelings to the side he advocates; 430 how he brings his accumulated store of historical illustrations to his aid, under the guidance of both the positive and the negative tact of the orator; saying everything to gain, and nothing to alienate the dispositions that he has carefully measured.

431 After Erskine and Macaulay have yielded their first

contribution to the oratorical student, he could turn with profit to Burke, who has the materials of oratory in the same high order as Macaulay, 432 but who in the employment of them so often miscarries-- sometimes partially, at other times wholly. 433 It then becomes an exercise to distinguish his successes from his failures; to resolve these into their elementary merits and defects, according to the oratorical scheme. 434 The close study of one or two orations is still the preferable course; and the most profitable transition from the Burke sample is to the selected speech or speeches of some other orator as Canning or Brougham. 435 All the time, the pupil must be enlarging and improving his analytic scheme, which is the means of keeping his mind to the point in hand, amid the distraction of the orator's gorgeous material.

436 The subsequent stages of oratorical study are much plainer than the commencement. 437 A time comes when the pupil will roam freely over the great field of oratory, modern and ancient, knowing more and more exactly what to appropriate and what to neglect. 438 You will be quite aware of the necessity of rivalling the great masters in resources of knowledge on the one hand, and of style on the other; but you will look for these elsewhere, as well as in the professed orators.

EXAMPLES OF PERSUASIVE ART

439 Moreover, as the persuasive art is exemplified in people that have never been public speakers, the oratorical pupil will make a selection from the most influential of this class. 440 You will find, for example, in the argumentative treatises of Johnson, in the Letters of Junius, in the writings of Godwin, in Sydney Smith, in Bentham, in Cobbett, in Robert Hall, in Fonblanque, in J.S. Mill, in Whately, 441 and a host besides, the exemplification of oratorical merits, together with materials that are of value. 442 It is understood, however, that the search for materials and the acquisition of oratorical form, are not made to advantage on the same lines, and,

for this and other reasons, should not go together.

443 The extreme test of the principle of concentration as against equal application, is the acquirement of Style, or the extending of our resources of diction and expression in all its particulars. 444 Being a matter of endless minute details, we may feel ourselves at a loss to compass it by the intensive study of a narrow and select example. 445 Still, with due allowance for the speciality of the case, the principle will still be found applicable. 446 We should, however, carry along with us, the maxim exemplified under oratory, of separating in our study, as far as may be, the style from the matter. 447 We begin by choosing a treatise of some great master. We may then operate either (1) by simple reading and re-reading, or (2) by committing portions to memory 'verbatim', or (3), best of all, by making some changes according to an already acquired ideal of good composition. 448 This to shows the great importance of attaining as early as possible some regulating principles of goodness of style: 449 the action and reaction of these, on the most exemplary authors, constitute our progress in the art, and, in the quickest way, store the memory with the resources of good expression.

ECONOMICS OF BOOK READING

450 The head just now finished includes really by far the greatest portion of the economy of study. 451 There are various other devices of importance in their way, but much less liable to error in practice. 452 Of these, a leading place may be assigned to the best modes of Distributing the Attention in reading. 453 Such questions as the following present themselves for consideration to the earnest student. How many distinct studies can be carried on together? What interval should be allowed in passing from one to another? 454 How much time should be given to the art of reading, and how much to subsequent meditating or ruminating on what has been read? 455 These points are all susceptible of being determined, within

moderate limits of error. 456 As to the first, the remark was made by Quintilian, that, in youth, we can most easily pass from one study to another. 457 The reason of this, however, is, that youth does not take very seriously to any study. 458 When a special study becomes engrossing, the alternatives must rather be recreative than acquisitive; 458 not much progress being made in what is slighted, or left over to the exhaustion caused by attention to the favourite topic. 459 A more precise answer can be made to the second and third queries, namely, as to an interval for recall and meditation, after putting down a book, and before turning the attention into other channels. 460 There is a very clear principle of economy here. We should save as far as possible the fatigue of the reading process, or make a given amount of attention to the printed page yield the greatest impression on the memory. 461 This is done by the exercise of recalling without the book; an advantage that we do not possess in listening to a lecture, until the whole is finished, when we have too much to recall. 462 To hurry from book to book is to gain stimulation at the cost of acquisition.

463 I have alluded to the case of an engrossing subject, which starves all accompanying studies. 464 There are but two ways of obviating the evil, if it be an evil; which it indeed becomes, when the alternative demands also are legitimate. 465 The one is peremptorily to limit the time given to it daily, so as to rescue some portion of the strength for other topics. 466 The other is to intermit it wholly for a certain period, and let other subjects have their swing. 467 In advancing life, and when our studious leisure is only what is left from professional occupation, two different studies can hardly go on together. 468 The alternative of a single study needs to be purely recreative.

469 One other point may be noted under this head. In the application to a book of importance and difficulty, there are two ways of going to work: to move on slowly, and master as we go; or to move on quickly to the end, and begin again. 470 There is most to be said for the first method, although

distinguished people have worked upon the other. 471 The freshness of the matter is taken off by a single reading; the re-reading is so much flatter in point of interest. 472 Moreover, there is a great satisfaction in making our footing sure at each step, as well as in finishing the task when the first perusal is completed. 473 We cannot well dispense with re-reading, but it need not extend to the whole; marked passages should show where the comprehension and mastery are still lagging.

DESULTORY READING

474 Another topic is Desultory Reading. This is the whole of the reading of the unstudious mass; it is but a part of the reading of the true student. 475 It may mean, for one thing, jumping from book to book, perhaps reading no one through, except for pure amusement. 476 It may also include the reading of periodicals, where no one subject is treated at any length. 477 As a general rule, such reading does not give us new foundations, or constitute the point of departure of a fresh department of knowledge; 478 yet the amount of labour and thought bestowed upon articles in periodicals, may render them efficacious in adding to a previous stock of materials, or in correcting imperfect views.

479 The truth is, that to the studious person, the desultory is not desultory. The only difference with you is that you have two attitudes that you may assume--the severe and the easy-going; 480 the one is most associated with systematic works on leading subjects; the other with short essays, periodicals, newspapers, and conversation. 481 In this last attitude, which is reserved for hours of relaxation, you skips matters of difficulty, and absorbs scattered and interesting particulars without expressly aiming at the solution of problems or the discussion of abstract principles. 482 There is no reason why an essay in a periodical, a pamphlet, or a speech in Parliament, may not take a first place in anyone's education. 483 All the labour and resource that go to form a work of magnitude may

be concentrated in any one of these. 484 Still, they are presented in the form that we are accustomed to associate with our desultory work, and our times of relaxation; and so, they seldom produce in the minds of readers the effect that they are capable of producing. 485 The thorough student will not fail to extract materials from one and all of them, but even you will scarcely choose from such sources the text for the commencement of a new study.

486 The desultory is not a bad way of increasing our resources of expression. 487 Although there be a systematic and a best mode of acquiring language, there is also an inferior, yet not ineffective mode; namely, reading copiously whatever authors have at once a good style and a sustaining interest. 488 Hence, for this purpose, shifting from book to book, taking up short and light compositions, may be of considerable value; 489 anything is better than not reading at all, or than reading compositions inferior in point of style. 490 The desultory person will not be without a certain flow of language as well as a command of ideas; notwithstanding which, you will never be confounded with the studious person.

491 A fifth point is the proportion of book-reading to Observation of the facts at first hand. 492 From want of opportunity, or from disinclination, many persons have all their information on certain subjects cast in the bookish mould, and do not fully conceive the particular facts as these strike the mind in their own character. 493 A reader of History, with no experience of affairs, is likely to have imperfect bookish notions; just as a person of affairs, not a reader, is subject to narrowness of another kind. 494 It was remarked by Sir G. Cornewall Lewis, that the German historians of the Athenian Democracy write like people that never had any actual experience of popular assemblies. 495 A lawyer must be equally versed in principles and in cases as heard in court: this is a type of knowledge generally. 496 In the Natural History Sciences, observation and reading go hand in hand from the first. 497 In the science of the Human Mind, there

are general doctrines, contrived to embrace the world of mental phenomena: 498 the student may have to begin with these, and work upon them exclusively for a time, 499 but in the end, phenomena must be independently viewed by you in their naked character, as exhibited directly in your own mind, and inferentially in the minds of those that fall under your observation. 500 Book knowledge of Disease has to be coupled with bed-side knowledge; neither will take the place of the other.

501 I began by limiting the meaning of study to the reading of books, and have reviewed the various points in the economy of this process. 502 The other means of attaining, enlarging, deepening our knowledge, namely, Observation of facts, Conversation, Disputation, Composition, have each an art of its own-- especially Disputation, which has long been reduced to rule. 503 Observation also admits of specific directions, but, in stating the necessity of combining observation with book theories and descriptions, I have assumed the knowledge of how to observe.

AIDS OF CONVERSATION AND COMPOSITION

504 Of all the adjuncts of study, none is so familiar, so available, and, on the whole, so helpful, as Conversation. 505 The authors of Guides to Students, as Isaac Watts, give elaborate rules for carrying on conversation, a good many of them being more moral than intellectual; 506 but an art of conversation would be very difficult to formulate; it would take quite as long an essay as I have devoted to study, and even then would not follow half of the windings of the subject. 507 The only notice of it that my plan requires, is such as I have already bestowed upon Observation: 508 namely, to point out the advantage of combining a certain amount of reading with, conversation; a thing that almost everybody does according to their opportunities.

509 To rehearse what we have read to some willing and sympathising listener, is the best way of impressing the memory and of clearing up difficulties to the

understanding. 510 It brings in the social stimulus, which ranks so high among human motives. 511 It is a wholesome change of attitude; relieving the fatigue of book-study, while adding to its fruitfulness. 512 Even beginners in study are mutually helpful, by exchanging the results of their several book acquirements; while it is possible to raise conversation to the rank of a high art, both for intellectual improvement and for mutual delectation. 513 I cannot say that the ideal is often realised; since two or more must combine to conversation, and it is not often that the mutual action and re-action is perfectly adjusted for the highest effect.

514 The last great adjunct of study is original Composition, which also would need to be formulated distinct from the theory of book-study. 515 Viewed in the same way as we have viewed the other collateral exercises, one can pronounce it to an invaluable adjunct to book-reading, as well as an end in itself; 516 it is a variation of effort that diverts the mental strain, and re-acts powerfully upon the extraction of nutriment from books. 517 Besides the pride of achievement, it evokes the social stimulus with the highest effect; our compositions being usually intended for some listeners. 518 But, when to begin the work of original composition, as distinct from the written exercises upon books, in the way of abstracting, amending, and the rest; 519 what forms it should assume at the outset, and by what steps it should gradually ascend to the culminating effects of the art,--would all admit of expansion and discussion as an altogether separate theme.

520 Enough to remark here, that a course of book-reading without attempts at original composition is as faulty an extreme, as to begin and carry on writing upon a stinted basis of reading. 521 The thorough student, as concerned in the Panagogue, carrying on book-study in the manner I have sketched, will almost infallibly end, at the proper time, in a self-thinker, and a self-originator. 522 An adequate familiarity with the great writers of the past both checks presumptuous or hasty efforts of reproduction, 523 and

encourages modest attempts of our own as we feel ourselves becoming gradually invigorated through the combined influence of all the various modes of well-directed study.

RELIGIOUS TESTS AND SUBSCRIPTIONS

Alexander Bain

16 Every person has an interest in arriving at truth for the self. 2 However useful it may be to mislead other people, however sweet to look down from a height on the erring throng beneath, it is neither useful nor sweet to be ourselves at sea without a compass. 3 We may not care to walk by the light we have, but we do not choose to exchange it for darkness.

4 This reflection is most obvious with reference to the order of Nature. Our life depends on adapting means to ends; which supposes that we know cause and effect in the world around us. 5 A long story is cut short by the adage, "Knowledge is power"; otherwise rendered, "Truth is bliss".

6 The bearing of truth is free from all doubt when the problem is, how to gain certain ends-- how to be fed, how to get from one place to another, how to cure disease. A new case is presented by the choice of ends. 7 The tyrannical French minister, when appealed to by a starving peasantry in the terms, "We must live," replied, "I do not see the necessity". 8 There was here no question of true and false, no problem for science to solve. It was a question of ends, and could not be re-argued. 9 The only possible retort was to ask, "What does your Excellency consider a necessity?" 10 If the reply were, "That I and my King may rule France and be happy," then might the starving wretches find some aid from a political scientist who could show that, in the order of Nature, ruler and people must stand or fall together. 11 So, it is no question of true or false in the order of Nature, whether I shall adopt, as the end of life, my own gratification purely, the good of others purely, or part of both.

12 In like manner the Benthamite, who propounds happiness as the general end of human society, cannot prove this, 13 as Newton could prove that gravity follows the inverse square of the distance; nor can his position be impugned in the way that Newton impugned the vortices of Descartes, by showing that they were at variance with fact.

14 There is a third case. Assertions are made out of the sphere of the sensible world, and beyond the reach of verification by the methods of science. 15 There is a region of the supersensible or supernatural, where cause and effect may be affirmed and human interests involved, but where we cannot supply the same evidence or the same confutation as in sublunary knowledge. 16 That all human beings shall have an existence after death is matter of truth or falsehood, 17 but the evidence is of a kind that would not be adduced for proving that a caterpillar becomes a butterfly or that a seed turns to a plant. 18 The reasoning employed, no doubt, makes references to facts of the order of Nature; but it is circuitous and analogical, and is admitted merely because better cannot be had.

THREE DIFFERENT CLASSES OF ASSERTIONS

19 The peculiarity of this last class of affirmations is that they give great room for the indulgence of our likings. 20 So little being fixed with any precision, we can shape our beliefs to please ourselves. 21 Even as regards the sensible world, we can sometimes accommodate our views to what we wish, as when we assume that our favourite foods and stimulants are wholesome; 22 but such license soon meets with checks in the physical sphere, while there are no such checks in the realms of the super-physical.

23 Now, in all these three departments of opinion, the interest of humankind lies in obtaining the best views that can possibly be obtained. 24 As regards the first and third-- the region of true and false, one in the sensible, the other in the supersensible world-- we are

clearly interested in getting the truth. 25 As regards the second-- the region of ends-- if there be one class of ends preferable to another, we should find out that class.

26 The only doubt that can arise anywhere is, whether in the third case-- the case of the supernatural,-- truth is of the same consequence to us. 27 Such a doubt, however, begs the whole question at issue. If the truth be of no consequence here, it is because we shall never be landed in any reality corresponding to what is declared: 28 that the nature of the future life is purely imaginary and not to be converted into fact; in other words, that there is no future life; 29 that there is merely a land of dreams and fiction, which can never be proved true and never proved false.

30 It would then be a projection of thought from the present life, and would cease with that life. 31 All that people could claim in the matter would be the liberty of imagination; and this being so, we are not to be committed to any one form. 32 In short, we are to picture what we please in a world that cannot be made out to exist. 33 The point is not, to be true or false; it is, to be well or ill imagined.

34 What, then, is to be the criterion of proper or improper imagination? 35 On what grounds are we to make our preference between the different schemes of the super-sensible world? 36 Is each one of us to be free to imagine for ourselves, or are we to submit to the dictation of others? 37 These questions lead up to another. How far are the interests of the present life concerned in the form given to our conceptions of a future life?

38 It would seem to be an unanswerable assumption that, in all the three situations above supposed, we should do the very best that the case admits of. 39 In the order of Nature we should get, as far as possible, the truth and the whole truth; 40 in the choice of ends for this life we should embrace the best ends; 41 in the shaping of another life we should be free to follow out whatever may be the course suitable to the operation.

METAPHYSICS

EARLY SOURCES
OF INTOLERANCE

42 The means for arriving at truth in the order of Nature is an active search according to certain well-known methods. 43 It farther involves the negative condition of perfect freedom to canvass, to controvert, or to refute, every received doctrine or opinion. 44 There is no use in going after new facts, or in rising to new generalities, if we are not to be allowed to displace errors. 45 This is now conceded, except at the points of contact of the natural and the supernatural. 46 In spite of the wide separation of the two worlds-- the world of fact and the world of imagination,-- we cannot conceive the second except in terms of the first; 47 and if the shaping of the supernatural acquires fixity and consecration, the natural facts made use of in the fabric acquire a corresponding fixity, even although the rendering is found to be inaccurate. 48 The prevailing conception of a future life needs a view of the separate and independent subsistence of the mental powers of human, very difficult to reconcile with present knowledge.

49 The growth of intolerance is quite explicable, but the explanation is not necessarily a justification. 50 Although every division of the human family must have passed through many social phases, and must therefore have experienced revolutionary shocks, 51 yet the rule of human's existence has been a rigorous fixity of institutions, with a hatred of change. 52 Innovations, when not the effect of conquest, would be made under the pressure of some great crisis, or some tremendous difficulty that could not otherwise be met. 53 The idea of individuals being allowed, in quiet times, to propose alterations in government, in religion, in morals, or even in the common arts of life, was thought of only to be stamped out. 54 There was a step in advance of the ancient and habitual order of things, when an innovating citizen was permitted to make own proposal to the assembled tribe, with a rope about the neck, to be drawn tight if one failed to convince own audience. 55 This might make people think

twice before advancing new views, but it was not an entire suppression of them.

56 The first introduction of the great religions of the world would in each case afford an interesting study of the difficulties of change and of the modes of surmounting these difficulties. 57 There must always have concurred at least two things,-- general uneasiness or discontent from some cause or other; 58 and the moral or intellectual ascendency of some one person, whose views, although original, were yet of a kind to be finally accepted by the people. 59 These conditions are equally shown in political changes, and are historically illustrated in many notable instances. It is enough to cite the Greek legislation of Lycurgus and of Solon.

60 Such changes are the exceptions in human affairs; they occur only at great intervals. 61 In the ordinary course of societies, the governing powers not merely adhere to what is established, but forbid under severe penalties the very suggestion of change. 62 The chronic misery of the race is compatible with unreasoning acquiescence in a state of things once established; incipient reformers are at once immolated ‘pour encourager les autres’. 63 It is the aim of governments to make themselves superfluously strong; they take precautions against unfavourable ideas no less than against open revolt. 64 In this, they are seconded by the general community, which would make things too hot even for a reforming king.

SEPARATION OF RELIGION FROM POLITICS

65 It is said by the evolution or historical school of politicians, that this was all as it should be. The free permission to question the existing institutions, political and religious, would have been incompatible with stability. 66 In early society more especially, religion and morality were a part of civil government; a dissenter in religion was the same thing as a rebel in politics; the distinction between the civil and the religious could not yet be drawn.

67 Without saying whether this was the case or not-- for I should not like to commit myself to the position, "Whatever was, was right" at the time-- 68 I trust we are now far on the way to being agreed that the civil and the religious are no longer to be identified; that the State, as a state, is not concerned to uphold any one form of religious belief. 69 Modern civilised communities are believed capable of existing without an official religion; the citizens being free to form themselves into self-governed religious bodies, as various as the prevailing modes of religious belief. 70 It may be long ere this goal be fully reached; but even the upholders of the present state religions admit that, supposing these were not in existence, nobody would now propose to institute them.

71 The foregoing remarks may appear somewhat desultory, as well as too brief for the extent of the theme. 72 They must be accepted, however, as an introduction to a more limited topic, which presupposes in some measure the general principle of toleration by the state of all forms of religious opinion. 73 Whether with or without established religions, perfect freedom of dissent is now demanded, and, with some hankering reservations, pretty generally conceded. 74 Individuals are allowed to congregate into religious societies, on the most various and opposite creeds.

75 So far good. Yet there remains a difficulty. Long before the age of toleration, when each state had an established religion, the people in general formed their habits of religious observance in connection with the State Church-- 76 its doctrines, its ritual, its buildings, and its sacred places. 77 When disruption took place, the separatists formed themselves into societies on the original model, merely dropping the matters of disagreement. 78 Fixity of creed and of ritual was still enacted; the only remedy for dissatisfaction on either subject was to swarm afresh, and set up a new variety of doctrine or of ritual, to which a rigid adherence was still expected as a condition of membership.

79 By this costly and troublesome process, Churches have been

multiplied according to the changes of view among sections of the community. 80 A certain energy of conviction has always been necessary to such a result. 81 Equally great changes of opinion occur among members of the older Church communities, without inducing them to break with these; so that nominal membership ceases to be a mark of real adhesion to the articles of belief.

EVILS OF PENAL RESTRAINT ON DISCUSSION

82 These few commonplaces are meant to introduce the enquiry-- now a pressing one-- whether, and how far, fixed creeds are desirable or expedient in religious bodies generally; 83 no difference being made between state Churches and voluntary Churches. This is the question of Subscription to Articles by the clergy.

84 Let us now review the evils attendant on subscription, and next consider the objections to its removal. 85 In the first place, the process of restraining discussion by penal tests is inherently untenable, absurd, and fallacious.

86 In support of this strong assertion, we have only to repeat, that every person has an interest in getting at the truth, and consequently in whatever promotes that end. 87 We live by the truth; error is death. To stand between a person and the attainment of truth, is to inflict an injury of incalculable amount. 88 The circumstances wherein the prohibition of truth is desirable, must be extraordinary and altogether exceptional. 89 The few may have a self-interest in withholding truth from the many; neither the few nor the many have an interest in its being withheld from themselves. 90 Each one of us has the most direct concern in knowing on what plan this universe is constituted, what are its exact arrangements and laws. 91 Whether for the present life, or for any other life, we must steer our course by our knowledge, and that knowledge needs to be true. 92 Obstruction to the truth recoils upon the obstructors. To flee to the refuge of lies is not the greatest happiness of anybody.

93 It has been maintained that there are illusions so beneficial as to be preferable to truth. 94 Occasionally, in private life, we practise little deceptions upon individuals when the truth would cause some great temporary mischief. 95 This case need not be discussed. The important instance is in reference to religious belief. 96 A benevolent Deity and a future life are so cheering and consoling, it is said, that they should be secured against challenge or criticism; they ought not to be weakened by discussion. 97 This, of course, assumes that these doctrines are unable to maintain themselves against opponents, that, with all their intrinsic charm--which nobody can be indifferent to--, they would give way under a free handling. 98 Such a confession is fatal. People will go on cherishing pleasing illusions, but not such as need to be protected in order to exist. 99 According to Plato, the belief in the goodness of the Deity was of so great importance that it was to be maintained by state penalties--about the worst way of making the belief efficacious for its end. 100 What should we think of an Act passed to imprison whoever disputed the goodness of King Alfred, the Man of Ross, or Howard?

101 Granting that certain illusions are highly beneficial, it does not follow that they are to be exempted from criticism. Their effect depends on the prestige of their truth. That is, they must have reasons on their side. 102 But a doctrine is not supported by reasons, unless the objections are stated and answered; not sham objections, but the real difficulties of an enquiring mind. 103 If the statement of such difficulties is forcibly suppressed, the rational foundations will sooner or later be sapped.

FREEDOM ESSENTIAL TO THE SEARCH FOR TRUTH

104 If illusions are themselves good, freedom of thought will give us the best. 105 Why should we protect inferior illusions against the discovery of the superior? 106 The unfettered march of the intellect may improve the quality

of our illusions as illusions, while also strengthening their foundations. 107 If religion be a good thing, the best religion is the best thing; and we cannot be sure of having the best, if people are forbidden to make a search.

108 Supposing, then, truth is desirable, the means to the end are desirable. Now one of the means is perfect liberty to call in question every opinion whatsoever. 109 This is not all that is necessary; it is not even the principal condition of the discovery of new truth. It is, however, an indispensable adjunct, a negative condition. 110 While labourious search for facts, care in comparing them, genius in detecting deep identities, are the highways to knowledge,-- the permission to promulgate new doctrines and to counter-argue the old is equally essential. 111 People cannot be expected to go through the toil of making discoveries at the hazard of persecution. If a few have done so, it is their glory and everybody else's shame.

112 That the torch of truth should be shaken till it shine, is generally admitted. Still, exceptions are made; otherwise the present argument would be superfluous. 113 On certain subjects there is a demand for protection against innovating views. The implication is that, in these subjects, truth is better arrived at by delegating the search to a few, and treating their judgment as final. 114 I need not ask where we should have been, if this mode of arriving at truth had been followed universally. 115 The monopoly of enquiry claimed for the higher subjects, if set up in the lower, would be treated as the empire of darkness.

116 Second. The subscription to articles, and the enforcement of a creed by penalties, are nugatory for their own purpose; they fail to secure uniformity of belief.

117 This is shown in various ways. For instance, to inculcate adhesion to a set of articles, is merely to ensure that none shall use words that formally deny one or other of the doctrines prescribed. 118 It does not say, that the subscriber shall teach the whole round of doctrines, in their due order and proportion. 119 A preacher may at pleasure omit from own pulpit discourses any single doctrine; so that, in so far as own ministrations

are concerned, to the hearers such doctrine is non-existent; without being denied, it is ignored. 120 Against omission, a prosecution for heresy would not hold. In this way, the clergy have always had a certain amount of liberty, and have freely used it. 121 In so doing, they have altered the whole character of the prescribed creed, without being technically heterodox. 122 Everyone of us has listened to preachers of this description. Some ignore the Trinity, some the Atonement; many nowadays, without denying future punishment, never mention hell to ears polite. 123 If the rigorous exclusion of a leading doctrine should excite misgivings, a very slight, formal, and passing admission may be made, while the stress of exhortation is thrown upon quite different points.

SUBSCRIPTION FAILS TO ATTAIN ITS END

124 To attain a conviction for heresy, involving deprivation of office, the forms of justice must be respected. 125 It is only under peculiar circumstances, that the ecclesiastical authority can be content with saying, "I do not like thee, Dr. Fell, or Dr. Smith, and I depose thee accordingly". 126 A regular trial, with proof of specific contradiction of specific articles, allowing the accused the full benefit of own explanations, must be the rule in every corporation that respects justice. 127 In the Church of England, a person cannot be deprived unless you contradict the articles clearly and consistently; 128 the smallest incoherence on your part, the slightest vacillation in the rigour of your denial, is enough to save you. 129 We may easily imagine, therefore, how widely a clergyman may stray from the fair, ordinary, current rendering of the doctrines of the Church, without danger. 130 The whole essence of Christianity may be perverted under a few cunning precautions and by observing a few verbal formalities. 131 It has been pointed out, many times over, that the legally imposed creeds were the creatures of accident and circumstances at the time of their enactment, 132 and are wholly unsuitable to the

conservation of the more permanent and essential articles of the Christian faith. 133 The amount of heresy, as against the more truly representative doctrines, that may pass through their meshes is very great.

134 This weakness is aggravated by another-- the want of any provision for amending the creed from time to time. 135 If it were desirable to adopt measures for maintaining uniformity of opinions among the clergy, the creed should be excised, or added to, according to the needs of every age. 136 That this is not done, shows that the machinery of tests is altogether abnormal; it is not within the type of regular legislation. 137 That any given creed should be regarded as out of keeping, as both redundant and defective, and yet that the ecclesiastical authority should shrink from applying a remedy to its most obvious defects, proves that the system itself is bad. 138 All healthy legislation lends itself to perpetual improvement; that the enactments of articles of belief cannot be reconsidered, is a sign of rottenness.

139 A third objection to tests is, that mere dogmatic uniformity, if it were more complete than any tests can make it, is at best but a part of the religious character. 140 It does nothing to secure or promote fervour, feeling, the emotional element in religion. 141 It is by moral heat, far more than by its mould of doctrine, that religion influences humankind. 142 There is no means of censuring preachers for coldness or languid indifference; or rather, there is another and more legitimate means than penal prosecutions, namely, expressed dissatisfaction and the preference of those that excel in the quality. 143 A warm, glowing manner, an unctuous delivery, commands hearers and conducts to popularity and importance. 144 The people of cold and unfeeling natures may get into office, but they are lightly esteemed. 145 They are not had up to a public trial and deposed, but they are treated, and spoken of, in such a way as to discourage people of their type from becoming preachers, and to encourage the other sort. 146 There are many qualifications that go to forming a good preacher; the

holding of the creed of the body is only one. 147 Yet, with the exception of gross immorality or abandonment of duty, correctness of creed is the only one that is subjected to the extreme penalty of loss of office; the others are secured by different means. 148 Is it too much to infer that, without the extreme penalty, a reasonable conformity to the prevailing creed might also be secured?

ELEMENT OF FEELING NOT SECURED

149 The importance of the element of feeling has been most perceived in times when the religious current was strongest. 150 At these times, its expression would not be hemmed in by rigorous formulas. 151 The first communication of religious doctrines has always partaken of a broad and free rendering; apparent discrepancies were disregarded. 152 To reduce all the utterances of the prophets and the apostles to definite forms and rigid dogmas, was to misconceive the situation. 153 We may well suppose that the New Testament writers would have refused to subscribe the Athanasian Creed or the Westminster Confession; 154 not because these were in flat contradiction to Scripture, but because the way of embodying the religious verities in these documents would be repugnant to their ideas of form in such matters. 155 The creed-builders may have been never so anxious to give exact equivalents of the original authorities; 156 yet their fine distinctions and subtle logic would have, in all probability, been ranked by Paul and Peter among the latter-day perversions of the faith. 157 The very composition of a creed would have been as distasteful to the first century, as it is incongruous to the nineteenth.

158 The evil operation of religious tests, and of the accompanying intolerance of the public mind as shown towards any form of dissent from the stereotyped orthodoxy, admits of a very wide handling. 159 It is of course the problem of religious liberty. 160 Some parts of the argument need to be reproduced here, to help us in replying to the objections against

an unconditional abolition of compulsory creeds.

161 In conversing, many years ago, with the late Jules Mohl, the great Oriental scholar, professor of Persian in the College de France, I was much struck with his account of the nature of his duties as an expounder of the modern Persian authors. 162 These authors, for example the poet Sadi, were in creed adherents of the ancient Persian fire-worship, notwithstanding the Mohammedan conquest of their country. 163 They were, of course, forbidden to avow that creed directly; and in consequence, they had recourse to a form of composition by ‘doubles entendres’, veiling the ancient creed under Mohammedan forms. 164 Mohl's business, as their expounder, was to strip off the disguise and show the true bearings of the writers, under their show of conformity to the established opinions.

165 This is a typical illustration of what has happened in Europe for more than two thousand years. The first recorded martyr to free speculation in philosophy was Anaxagoras in Greece. 166 Muleted in the sum of five talents, and expelled from Athens, he was considered fortunate in being allowed to retire to Lampsacus and end his days there. 167 His fate, however, was soon eclipsed by the execution of Socrates,-- an event whereby the Athenian burghers were enabled to bias the expression of free opinions from that time to this. 168 The first person to feel the shock was Plato. That he was affected by it, to the extent of suppressing his views on the higher questions, we can infer with the greatest probability.

CONSEQUENCES OF THE EXECUTION OF SOCRATES

169 Aristotle was equally cowed. A little before his death, the chief priest of Eleusis, following the Socratic precedent, entered an indictment against him for impiety. 170 This indictment was supported by citations of certain heretical doctrines from his published writings; 171 on which Grote makes the significant remark, that his paean in honour of

his friend Hermeias would be more offensive to the feelings of an ordinary Athenian citizen than any philosophical dogma extracted from the ‘cautious prose compositions’ of Aristotle. 172 That is to say, the execution of Socrates was always before his eyes; he had to pare his expressions so as not to give offence to Athenian orthodoxy. 173 We can never know the full bearings of such a disturbing force. The editors of Aristotle complain of the corruptness of his text; a far worse corruptness lies behind. 174 In Greece, Socrates alone had the courage of his opinions. While his views as to a future life, for example, are plain and frank, the real opinion of Aristotle on the question is an insoluble problem. 175 Now, considering the enormous sway of Aristotle in modern Europe,-- how desirable was it that his real sentiments had reached us unperverted by the Athenian burgher and the hemlock!

175 It would be too adventurous to continue the illustration in detail through the Christian ages. 176 It is well known that the later schoolmen strove to represent reason as against authority, but wrote under the curb of the Papal power; hence their aims can only be divined. A modern instance or two will be still more effective.

177 It can at last be clearly seen what was the motive of Carlyle's perplexing style of composition. 178 We now know what his opinions were, when he began to write, and that to express them then would have been fatal to his success; yet he was not a man to indulge in rank hypocrisy. 179 He, accordingly, adopted a studied and ambiguous phraseology, which for long imposed upon the religious public, who put their own interpretation upon his mystical utterances, and gave him the benefit of any doubts.

180 In the "Life of Sterling" he threw off the mask, but still was not taken at his word. 181 Had there been a perfect tolerance of all opinions he would have begun as he ended; and his strain of composition, while still mystical and high-flown, would never have been identified with our national orthodoxy.

182 I have grave doubts as to whether we possess Macaulay's real opinions on religion. 183 His way of dealing with the subject is so like the hedging of an unbeliever that, without some good assurance to the contrary, I must include him also among the imitators of Aristotle's "caution". 184 Some future critic will devote the self, like Professor Mohl, to expounding own ambiguous utterances.

EVIL
OF DISFRANCHISING THE CLERGY

185 When Sir Charles Lyell brought out his "Antiquity of Man" he too was cautious. 186 Knowing the dangers of his footing, he abstained from giving an estimate of the extension of time required by his evidences of human remains. 187 Society in London, however, would not put up with that reticence, and he had to disclose at dinner parties what he had withheld from the public-- 188 namely, that, in his opinion, the duration of human could not be less than fifty thousand years.

189 These few instances must suffice to represent a long history of compelled reticence on the part of the people best qualified to instruct humankind. 190 The question now is-- What has been gained by it? What did the condemnation of Socrates do for the Athenian public? What did the chief priest of Eleusis hope to attain by indicting Aristotle? 191 Unless we can show, as is no doubt attempted, that the set of opinions that happen to be consecrated at any one time, whether right or wrong, were essential to the existence of society,-- 192 then the attempt to improve upon them was truly meritorious, instead of being censurable. 193 If the good of society as a whole is not plainly implicated, there remains only the interest of the place-holders under the existing system, as opposed to the interest of the mass of the people, who are, one and all, concerned in knowing the truth.

194 Again contracting the discussion to the narrow limits of the title of the essay, I must urge the special injury done to humankind by disfranchising the

whole clerical class; 195 that is to say, by depriving their authority of its proper weight in matters of faith. 196 It is an incontrovertible rule of evidence, that the authority of an interested party is devoid of worth. 197 Reasons are good in themselves, whoever utters them; but in trusting to authority, apart from reason, we need a disinterested authority. 198 This the clergy at present are not, except on the points left undecided by the articles. If a person has five thousand a year, conditional on holding certain views, the holding those views says nothing in their favour. 199 For a much less bribe, plenty of people can be 'got to maintain any opinions whatsoever. 200 When to this is added that, for certain other views, the holders are subjected to loss-- it may be to fine, imprisonment, or death,-- the value of people's adhesion to the favoured creed, as mere authority, is simply ‘nil’.

201 Truth, honesty, outspokenness, are not so well established as virtues, that we can afford to subject them to discouragement. 202 The contrary course would be more for the general good in every way. When the law is intolerant in principle, people will be hypocrites from policy. 203 You cannot train children to speak the truth if, from whatever cause, they have an interest in deception. 204 A repressive discipline induces a coarse outward submission, but cannot reach the inward parts: it only engenders hatred, and substitutes for open revolt an insidious secret retaliation. 205 Those only that come under the generous nurture of freedom can be counted on for hearty and willing devotion. 206 If we would reap the higher virtues, we must sow on the soil of liberty. 207 Encourage a person to say whatever one thinks, and you make the most of the person; 208 for difficult questions, where the mind needs all its powers, there should be no burdensome 'caution' in giving out the results.

RELAXATION NOW PRESSING

209 The imposing of subscription has its defenders, and these have to be fairly met. First, however, let us advert to the reasons why

relaxation is more pressing now than formerly.

210 It is known that, among dissentients from the leading dogmas of the prevailing creed of Christendom, are to be included some of the most authoritative names of the last three centuries; 211 our present formulas would not have been subscribed by Bacon, Newton, Locke, Kant; unless from mere pliancy and for the sake of quiet, like Hobbes. 212 If they had been in clerical orders, and had freely avowed their opinions as we know them, they would have been liable to deposition. 213 Yet the difficulties that these men might feel were far less than those that now beset the profession of our prevailing creeds. 214 The advances of knowledge on all the subjects that come into contact with the various articles, as received by the orthodox Churches, may not, indeed, compel the relinquishment of those articles, but will force the holders to change front, to re-shape them in different forms. 215 To such necessary modification, the creeds are a fatal obstacle. On a few points, such as the Creation in six days, these have been found elastic. 216 The doctrine that death came by the fall has been explained away as spiritual death. This process cannot go much further, without too much paltering with obvious meanings. 217 The recently-proclaimed doctrine of the Antiquity of Man comes into apparent conflict with human's creation and fall, as set forth in Genesis, on which are suspended the most vital doctrines of our creed. 218 A reconciliation may be possible, but not without a very extensive modification of the scheme of the Atonement. 219 It is not necessary to press Darwin's doctrine of Evolution; the deficiency of positive proof for that hypothesis may always be pleaded, as against the havoc it would make with the more distinctive points of Christian doctrine. 220 But the existence of human on the earth, at the very lowest statement, must be carried back twenty thousand years; this is not hypothesis, but fact. 221 The record of the creation and the fall of man will probably have to be subjected to a process of allegorising, but with inevitable

loss. 222 Now, whoever refuses a matter of fact counts on being severely handled; it is a different thing to refuse an allegory.

223 The modern doctrine named the "struggle for existence" is the old difficulty, known as "the origin of evil," presented in a new shape. 224 It is rendered more formidable, as a stumbling-block to the benevolence of the Author of Nature, by making what was considered exceptional the rule. 225 It gathers up into one comprehensive statement the scattered occasions of misery, and reveals a system whereby the few thrive at the expense of the many. 226 The apologists for Divine goodness has thus an aggravation of their load, and needs to be freed from all unnecessary trammels in the shaping of their creed.

OPPOSING DOGMAS TO THE RECONCILED

227 It has not escaped attention, that the honours paid to the illustrious Darwin, are an admission that our received Christianity is open to revision. 228 In consequence of a few conciliatory phrases, Darwin has been credited with theism; nevertheless he has ridden rough-shod over all that is characteristic in our established creeds. 229 Can the creeds come scathless out of the ordeal?

230 It is passing from the greater to the less, to dwell upon the increasing difficulties connected with the Inspiration of the Bible. 231 The Church-of-Englander luckily escapes making shipwreck here; the legal interpretation of the formularies saves them. 232 Yet to humankind, generally, it seems necessary that a superior weight should attach to a revealed book; and the other Churches cling to some form of inspiration, notwithstanding the growing difficulties attending it. 233 Here too there must be more freedom given to the people that would extricate the situation. At all events, the doctrine should be made an open question. 234 Even Cardinal Newman suggests doubts as to its being an imperative portion of the creed.

235 The attacks made on all sides against the Miraculous element in religion will force on a change of

front. 236 When an eminent popular writer and sincere friend of the Church of England surrenders miracles without the slightest compunction, 237 it needs not the elaborate argumentation of "Supernatural Religion" to show that some new treatment of the question is called for. 238 But may it not be impossible to put the new wine into the sworn bottles?

239 Like most great innovations, the proposal to liberate the clergy from all restraint as to the opinions that they may promulgate, necessarily encounters opposition. We are, therefore, bound to consider the reasons on the other side.

240 These reasons may be quoted in mass. As regards Established Churches in particular, it is said there is a State compact or understanding with the clergy that they should teach certain doctrines and no other; 241 that if tests were abolished, there would be no security against the most extreme opinions; 242 people eating the bread of a Reformed Church might inculcate Romanism instead of Protestantism; the pulpits might give forth Deism or Agnosticism. 243 No sect could hope to maintain its principles, if the clergy might preach any doctrine that pleased themselves. 244 More especially would it be monstrous and unjust, to allow the rich benefices of our highly endowed Church of England to be enjoyed by people whose hearts are in some quite different form of religion, 245 or no religion, and who would occupy themselves in drawing people away from the faith.

246 On certain assumptions, these arguments have great force. Clearly a person ought not to take pay for doing one thing and do something quite different. 247 When a body of religionists come together upon certain tenets, it would be a ‘reductio ad absurdum’ for any of its ministers to be occupied in denying and controverting these tenets.

248 All this supposes, however, that people will not be made to conform by any means short of prosecution and deprivation; 249 that the suspending of a severe penalty over people's heads is in itself a harmless device; 250 and that religious systems are now stereotyped to our satisfaction, so

that to deviate from them is mere wantonness and love of singularity. 251 Such are the assumptions that we feel called upon to challenge.

252 The plea that the Church has engaged itself to the State to teach certain tenets, in return for its emoluments and privileges, has lost its point in our time. 253 'L'état, c'est moi.' The Church and the State are composed of the same persons. Gibbon's famous ‘mot’ has collapsed. 254 'The religions of the Roman world,' he says, 'were all considered by the people as equally true, by the philosopher as equally false, and by the magistrate as equally useful'. 255 The people are now their own magistrates, and the true and the useful must contrive to unite upon the same thing. 256 If the Church feels subscription and fixity of creed a burden, it has only to turn its members to account in their capacity of citizens of the State to relieve itself. 257 If it silently ignores the creed, it is still responsible mainly to itself.

POSSIBLE ABUSES OF CLERICAL FREEDOM

258 The more serious objection is the possible abuse of the freedom of the clergy to utter opinions at variance with the prevailing creed. This position needs a careful scrutiny.

259 In the first place, the argument: supposes a condition of things that has now ceased. 260 When creeds were accepted in their literality by the bodies professing them, when the state of general opinion contained nothing hostile, and suggested no difficulties,-- 261 for any one member of a body to turn traitor may have well seemed mere perversity, temper, love of singularity, or anything but a wish to get at truth. 262 The offence assumed the character of a moral obliquity, and discipline can never be relaxed for immorality proper.

263 All the circumstances are now changed. The ministers and members of religious communities no longer cherish the same set of doctrines with only immaterial varieties; they no longer accept their articles in the sense of the original framers. 264 The body at

large has contracted the immoral taint; the whole head is sick; any remaining soundness is not with the acquiescent mass, but with the out-spoken individuals. 265 In such a state of things, ordinary rules are inapplicable. 266 There is a sort of paralysis of authority, an uncertainty whether to punish or to wink at flagrant heresy. 267 To say in such a case that the relaxation of the creed is not a thing to be proposed, is to confess, like Livy on the condition of Rome, that we can endure neither our vices nor their remedies.

268 Too much has at all times been made of individual divergences from the established creed. 269 The influence of a solitary preacher smitten with the love of heretical peculiarity has been grossly overrated. 270 The assumption is, that your own flock will, as a matter of course, follow their shepherd; 271 that is to say, the adhesion of individual congregations to the creed of the Church depends upon its being faithfully reproduced by their regular minister. 272 Such is not by any means the fact; the creed of the members of a Church is not at the mercy of any passing influence. 273 It has been engrained by a plurality of influences; one person did not make it, and one person cannot unmake it. 274 Moreover, allowance should be made for the spirit of opposition found in Church members, as well as in other people.

INDIVIDUAL DIVERGENCES UNIMPORTANT

275 It may be said that persons ought not to be subjected to the annoyance of hearing attacks upon their hereditary tenets, in which they expect to be more and more confirmed by their spiritual teacher. 276 This is of course, in itself, an evil. 277 We are not to expect ordinary people to recognise the necessity of listening to the arguments against their views, in order to hold these all the stronger. 278 If this height were generally reached, every Church would invite, as a part of its constituted machinery, a representative of all the heresies afloat; 279 a certain number of its ministers should be the avowed

champions of the views most opposed to its own-- ‘advocati diaboli’, so to speak. 280 There would then be nothing irregular in the retention of converts from its own number to these other doctrines. 281 It would be, however, altogether improper to found any argument on the supposition of such a state of matters.

282 It is an incident of every institution made up of a large collection of officials, that some one or more are always below the standard of efficiency, whence those that depend on their services must suffer inconvenience. 283 A great amount of dullness in preaching has always to be tolerated; so also might an occasional deviation from orthodoxy; 284 the more so, that the severity of the discipline for heresy has a good deal to do with the dullness.

285 If heretical tendencies have shown themselves in a Church communion, either they are absurd, unmeaning, irrelevant-- 286 perhaps a reversion to some defunct opinion,-- or they are the suggestion of new knowledge in theology, or outside of it. 287 In the first case, they will die a natural death, unless prosecution gives them importance; in the other case, they are to be candidly examined, to be met by argument rather than by deposition. 288 An individual heretic can always be neglected; if you are enthusiastic and able, you may have a temporary following, especially when the community has sunk into torpor. 289 If two or three in a hundred adopt erroneous opinions, it is nothing; if thirty or forty in a hundred have been led astray, the matter hangs dubious, and discretion is advisable. 290 When a majority is gained, the fullness of the time has arrived; the heresy has triumphed.

291 However strong may be the theoretical reasons for the abolition of the penal sanctions to orthodoxy, they do not dispense with the confirmation of experience; 292 and I must next refer to the more prominent examples of Churches constituted on the principle of freedom to the clergy.

THE ENGLISH PRESBYTERIAN CHURCH EXEMPLARY

293 The most remarkable and telling instance is that furnished by the English Presbyterian Church, with its coadjutor in Ireland. 294 The history of this Church is not unfamiliar to us; the great lawsuit relating to Lady Hewley's charity gave notoriety to the changes of opinion that had come over it in the course of a century. 295 But whoever is earnest on the question as to the expediency of tests should study the history thoroughly, as being in every way most instructive. 296 The leading facts, as concerns the present argument, are mainly these:-- First, the great decision at the Salters' Hall conference, on the 10th of March, 1719, when, by a majority of 73 to 69, it was resolved to exact no test from the clergy as a condition of their being ordained ministers of the body. 297 The point more immediately at issue was the Trinity, on which opinions had been already divided; but the decision was general. 298 The principle of the right of private judgment admitted of no exceptions.

299 Second. Long before this decision, the minds of the ministers had been ripening to the conviction, that creeds and subscriptions could do no good, and often did harm, indeed, the terms employed by some of them are everything that we now desire. 300 For example, Joseph Hunter, on the eve of the decision, wrote thus: "We have always thought that such human declarations of faith were far from being eligible on their own account, 301 since they tend to narrow the foundations of Christianity and to restrain that latitude of expression in which our great Legislator has seen fit to deliver His Will to us".

302 Third. Most remarkable is it to witness the consequences of this great act of emancipation. 303 A hundred and sixty-five years have elapsed-- a sufficient time for judging of the experiment. 304 The Presbyterian body at the time were made up partly of Arians, partly of Trinitarians, who held each other in mutual tolerance; the ministers freely exchanging pulpits. 305 No bad consequence followed. We do

not hear of individual ministers going to extravagant lengths in either direction. 306 A large body gravitated, in the course of time, to the modern Unitarian position; but, considering the start, the stride was not great.

307 In such a century as the eighteenth, there might well have been greater modifications of the creeds than actually occurred. 308 Evidently, in the absence of any compulsory adherence to settled articles, there was an abundant tendency to conservatism. 309 Commencing with Baxter, Howe, and Calamy, we find, in the course of the century, such names as Lardner, Price, Priestley, Belsham, Kippis, James Lindsay, Lant Carpenter—310 people of liberal and enlightened views on all political questions, and earnest in their good works. 311 These men's testimony to what is truth in religion, is of more value to us than the opinions of the creed-bound clergy. 312 Reason is still reason, but the weight of authority is with the free enquirers.

313 Fourth. The history of the Presbyterians answers a question that may be properly asked of the creed-abolitionist; namely, What bond is left to hold a religious community together? 314 The bond, in their case, simply was voluntary adhesion and custom. A religious community may hold together, like a political party, with only a vague tacit understanding. 315 When a body is once formed, it has an outward cohesion, which is quite enough for maintaining it in the absence of explosive materials. 316 The established Churches could retain their historical continuity under any modification of the articles. 317 By the present system, they have been habituated to take their creed as their legal definition; for that they could substitute their history and framework.

MODES OF TRANSITION FROM THE PRESENT SYSTEM

318 Various modes have been suggested for making the transition from the present system. One way is, to fall back upon the Bible as a test. This is the same as no test at all. 319 A person could not call the self a Christian minister, if you did not accept the

Bible in some sense; 320 and it would be obviously impracticable to frame a libel, and conduct a process for heresy, on an appeal to the Old and New Testaments at large. 321 The Bible may be the first source of the Christian faith, but other confluent streams have entered into its development; 322 and we must accept the consequences of a fact that we cannot deny. 323 However much religion may have to be broadened and liberalised, the operation cannot consist in reverting to the literal phraseology of the Bible.

324 A second method is, to prune away the portions of the creed that are no longer tenable. 325 It could not have been intended by the original framers of the creeds, that they should remain untouched for centuries. 326 With many Churches, there was a clear understanding that the formulas should be revised at brief intervals. The non-established Churches show a disposition to resume this power. 327 The United Presbyterian Church of Scotland has had the courage to make a beginning; still, relief will not in this way be given to minorities, and small changes do not correspond to the demands of new situations.

328 A more effectual mode is to discourage and suspend prosecutions for heresy. 329 The practice of heresy-hunting might be allowed to fall into disuse. Instead of deposing heretics, the orthodox champions should simply refute them.

330 In the Church of England, in particular, a change of the law may be necessary to give the desired relaxation. 331 The judges before whom heretics are tried are very exacting in the matter of evidence, but they cannot stop a prosecution made in regular form. 332 The Church of Scotland has more latitude in this respect, and has already given indications of entering on the path leading to desuetude.

The Fifth Book of Divine Panagogue called

MATTER

HUMAN OR MATTER
Ernst Lehrs

1 When I first made acquaintance with Rudolf Steiner and his work, I was finishing my academic training as an electrical engineer. 2 At the end of the 1914-18 war my first thought had been to take up my studies from where I had let them drop, four years earlier. 3 The war seemed to imply nothing more than a passing interruption of them. This, at any rate, was the opinion of my former teachers; 4 the war had made no difference whatever to their ideas, whether on the subject-matter of their teaching or on its educational purpose. 5 I myself, however, soon began to feel differently. It became obvious to me that my relationship to my subject, and therefore to those teaching it, had completely changed.

6 What I had experienced through the war had awakened in me a question of which I had previously been unaware; now I felt obliged to put it to everything I came across.

7 As a child of my age I had grown up in the conviction that it was within the scope of human to shape own life according to the laws of reason within you; 8 your progress, in the sense in which I then understood it, seemed assured by your increasing ability to determine your own outer conditions with the help of science. 9 Indeed, it was the wish to take an active part in this progress that had led me to choose my profession. 10 Now, however, the war stood there as a gigantic social deed which I could in no way regard as reasonably justified. 11 How, in an age when the logic of science was supreme, was it possible that a great part of humankind, including just those peoples to whom science had owed its origin and never-ceasing expansion, could act in so completely unscientific a way? 12 Where lay the causes of the contradiction thus revealed between human thinking and human doing?

13 Pursued by these questions, I decided after a while to give my studies a new turn. 14 The kind of

training then provided in Germany at the so-called Technische Hochschulen was designed essentially to give students a close practical acquaintance with all sorts of technical appliances; 15 it included only as much theory as was wanted for understanding the mathematical calculations arising in technical practice. 16 It now seemed to me necessary to pay more attention to theoretical considerations, so as to gain a more exact knowledge of the sources from which science drew its conception of Nature. 17 Accordingly I left the Hochschule for a course in mathematics and physics at a university, though without abandoning my original idea of preparing for a career in the field of electrical engineering. 18 It was with this in mind that I later chose for my Ph.D. thesis a piece of experimental research on the uses of high-frequency electric currents.

19 During my subsequent years of stuffy, however, I found myself no nearer an answer to the problem that haunted me. All that I experienced, in scientific work as in life generally, merely gave it an even sharper edge. 20 Everywhere I saw an abyss widening between human knowing and human action. 21 How often was I not bitterly disillusioned by the behaviour of humans for whose ability to think through the most complicated scientific questions I had the utmost admiration!

22 On all sides I found this same bewildering gulf between scientific achievement and the way people conducted their own lives and influenced the lives of others. 23 I was forced to the conclusion that human thinking, at any rate in its modern form, was either powerless to govern human actions, or at least unable to direct them towards right ends. 24 In fact, where scientific thinking had done most to change the practical relations of human life, as in the mechanisation of economic production, conditions had arisen which made it more difficult, not less, for people to live in a way worthy of human. 25 At a time when humanity was equipped as never before to investigate the order of the universe, and had achieved triumphs of design in mechanical constructions, human

life was falling into ever wilder chaos. Why was this?

26 The fact that most of my contemporaries were apparently quite unaware of the problem that stirred me so deeply could not weaken my sense of its reality. 27 This slumber of so many souls in face of the vital questions of modern life seemed to me merely a further symptom of the sickness of our age. 28 Nor could I think much better of those who, more sensitive to the contradictions in and around them, sought refuge in art or religion. 29 The catastrophe of the war had shown me that this departmentalising of life, which at one time I had myself considered a sort of ideal, was quite inconsistent with the needs of to-day. 30 To make use of art or religion as a refuge was a sign of their increasing separation from the rest of human culture. 31 It implied a cleavage between the different spheres of society which ruled out any genuine solution of social problems.

32 I knew from history that religion and art had once exercised a function which is to-day reserved for science, for they had given guidance in even the most practical activities of human society. 33 And in so doing they had enhanced the quality of human living, whereas the influence of science has had just the opposite effect. 34 This power of guidance, however, they had long since lost, and in view of this fact I came to the conclusion that salvation must be looked for in the first place from science. 35 Here, in the thinking and knowing of human, was the root of modern troubles; here must come a drastic revision, and here, if possible, a completely new direction must be found.

36 Such views certainly flew in the face of the universal modern conviction that the present mode of knowledge, with whose help so much insight into the natural world has been won, is the only one possible, given once for all to human in a form never to be changed. 37 But is there any need, I asked myself, to cling to this purely static notion of human's capacity for gaining knowledge? 38 Among the greatest achievements of modern science, does not the conception of evolution take a foremost place? 39

And does not this teach us that the condition of a living organism at any time is the result of the one preceding it, and that the transition implies a corresponding functional enhancement? 40 But if we have once recognised this as an established truth, why should we apply it to organisms at every stage of development except the highest, namely the human, where the organic form reveals and serves the self-conscious spirit?

41 Putting the question thus, I was led inevitably to a conclusion which science itself had failed to draw from its idea of evolution. 42 Whatever the driving factor in evolution may be, it is clear that in the kingdoms of Nature leading up to human this factor has always worked on the evolving organisms from outside. 43 The moment we come to human, however, and see how evolution has flowered in your power of conscious thought, we have to reckon with a fundamental change.

44 Once a being has recognised itself as a product of evolution, it immediately ceases to be that and nothing more. 45 With its very first act of self-knowledge it transcends its previous limits, and must in future rely on its own conscious actions for the carrying on of its development.

46 For me, accordingly, the concept of evolution, when thought through to the end, began to suggest the possibility of further growth in human's spiritual capacities. 47 But I saw also that this growth could no longer be merely passive, and the question which now beset me was: by what action of your own can human break your way into this new phase of evolution? 48 I saw that this action must not consist merely in giving outer effect to the natural powers of human thinking; that was happening everywhere in the disordered world around me. 49 The necessary action must have inner effects; indeed, it had to be one whereby the will was turned upon the thinking-powers themselves, entirely transforming them, and so removing the discrepancy between the thinker and the doer in modern human.

50 Thus far I could go through my own observation and reflexion, but no further. 51 To form a general idea of the deed on which

everything else depended was one thing; it was quite another to know how to perform the deed, and above all where to make a start with it. 52 Anyone intending to make a machine must first learn something of mechanics; 53 in the same way, anyone setting out to do something constructive in the sphere of human consciousness - and this, for me, was the essential point – must begin by learning something of the laws holding sway in that sphere. But who could give me this knowledge?

54 Physiology, psychology and philosophy in their ordinary forms were of no use to me, for they were themselves part and parcel of just that kind of knowing which had to be overcome. 55 In their various accounts of human there was no vantage point from which the deed I had in mind could be accomplished, for none of them looked beyond the ordinary powers of knowledge. 56 It was the same with the accepted theory of evolution; as a product of the current mode of thinking it could be applied to everything except the one essential - this very mode of thinking.

57 Obviously, the laws of the development of human consciousness cannot be discovered from a standpoint within the modern form of that consciousness. 58 But how could one find a viewpoint outside, as it were, this consciousness, from which to discover its laws with the same scientific objectivity which it had itself applied to discovering the laws of physical Nature?

59 It was when this question stood before me in all clarity that destiny led me to Rudolf Steiner and his work. 60 The occasion was a conference held in 1921 in Stuttgart by the Anthroposophical Movement; it was one of several arranged during the years 1920-2 especially for teachers and students at the Hochschulen and Universities. 61 What chiefly moved me to attend this particular conference was the title of a lecture to be given by one of the pupils and co-workers of Rudolf Steiner - 'The Overcoming of Einstein's Theory of Relativity'.

62 The reader will readily appreciate what this title meant for me. In the circles where my work lay, an intense controversy was

just then raging round Albert Einstein's ideas. 63 I usually took sides with the supporters of Einstein, for it seemed to me that Einstein had carried the existing mode of scientific thinking to its logical conclusions, whereas I missed this consistency among his opponents. 64 At the same time I found that the effect of this theory, when its implications were fully developed, was to make everything seem so 'relative' that no reliable world-outlook was left. 65 This was proof for me that our age was in need of an altogether different form of scientific thinking, equally consistent in itself, but more in tune with human's own being.

66 What appealed to me in the lecture-title was simply this, that whereas everyone else sought to prove Albert Einstein right or wrong, 67 here was someone who apparently intended, not merely to add another proof for or against his theory-there were plenty of those already - but to take some steps to overcome it. 68 From the point of view of orthodox science, of course, it was absurd to speak of 'overcoming' a theory, as though it were an accomplished fact, but to me this title suggested exactly what I was looking for.

69 Although it was the title of this lecture that drew me to the Stuttgart Conference-- circumstances prevented me from hearing just this lecture,-- 70 it was the course given there by Rudolf Steiner himself which was to prove the decisive experience of my life. 71 It comprised eight lectures, under the title: 'Mathematics, Scientific Experiment and Observation, and Epistemological Results from the Standpoint of Anthroposophy'; what they gave me answered my question beyond all expectation.

72 In the course of a comprehensive historical survey the lecturer characterised, in a way I found utterly convincing, the present mathematical interpretation of Nature as a transitional stage of human consciousness-- 73 a kind of knowing which is on the way from a past pre-mathematical to a future post-mathematical form of cognition. 74 The importance of mathematics, whether as a discipline of the human spirit or as

an instrument of natural science, was not for a moment undervalued. 75 On the contrary, what Rudolf Steiner said about Projective (Synthetic) Geometry, for instance, its future possibilities and its role as a means of understanding higher processes of Nature than had hitherto been accessible to science, 76 clearly explained the positive feelings I myself had experienced - without knowing why - when I had studied the subject.

77 Through his lectures and his part in the discussions - they were held daily by the various speakers and ranged over almost every field of modern knowledge-- I gradually realised that Rudolf Steiner was in possession of unique powers. 78 Not only did he show himself fully at home in all these fields; he was able to connect them with each other, and with the nature and being of human, in such a way that an apparent chaos of unrelated details was wrought into a higher synthesis. 79 Moreover, it became clear to me that one who could speak as he did about the stages of human consciousness past, present and future, must have full access to all of them at will, and be able to make each of them an object of exact observation. 80 I saw a thinker who was himself sufficient proof that human can find within the resources of own spirit the vantage-ground for the deed which I had dimly surmised, and by which alone true civilisation could be saved. 81 Through all these things I knew that I had found the teacher I had been seeking.

82 Thus I was fully confirmed in my hopes of the Conference; but I was also often astonished at what I heard. 83 Not least among my surprises was Rudolf Steiner's presentation of Goethe as the herald of the new form of scientific knowledge which he himself was expounding. 84 I was here introduced to a side of Goethe which was as completely unknown to me as to so many others among my contemporaries, who had not yet come into touch with Anthroposophy. 85 For me, as for them, Goethe had always been the great thinker revealing his thoughts through poetry. 86 Indeed, only shortly before my meeting with Rudolf Steiner it was in his poetry that Goethe had

become newly alive to me as a helper in my search for a fuller human experience of Nature and my fellow-humans. 87 But despite all my Goethe studies I had been quite unaware that more than a century earlier he had achieved something in the field of science, organic and inorganic alike, 88 which could help modern human towards the new kind of knowledge so badly needed to-day. 89 This was inevitable for me, since I shared the modern conviction that art and science were fields of activity essentially strange to one another. 90 And so it was again Rudolf Steiner who opened the way for me to Goethe as botanist, physicist and the like.

91 I must mention another aspect of the Stuttgart Conference which Belongs to this picture of my first encounter with Anthroposophy, and gave it special weight for anyone in my situation at that period. 92 In Stuttgart there were many different activities concerned with the practical application of Rudolf Steiner's teachings, and so one could become acquainted with teachings and applications at the same time. 93 There was the Waldorf School, founded little more than a year before, with several hundred pupils already.

94 It was the first school to undertake the transformation of anthroposophical knowledge of human into educational practice; later it was followed by others, in Germany and elsewhere. 95 There was one of the clinics, where qualified doctors were applying the same knowledge to the study of illness and the action of medicaments.

96 In various laboratories efforts were made to develop new methods of experimental research in physics, chemistry, biology and other branches of science. 97 Further, a large business concern had been founded in Stuttgart in an attempt to embody some of Rudolf Steiner's ideas for the reform of social life. 98 Besides all this I could attend performances of the new art of movement, again the creation of Rudolf Steiner and called by him 'Eurhythmy', 99 in which the astounded eye could see how noble a speech can be uttered by the human body when its limbs are moved in accordance with its

inherent spiritual laws. 100 Thus, in all the many things that were going on besides the lectures, one could find direct proof of the fruitfulness of what one heard in them.

101 Under the impression of this Conference I soon began to study the writings of Rudolf Steiner. Not quite two years later, I decided to join professionally with those who were putting Anthroposophy into outer practice. 102 Because it appeared to me as the most urgent need of the time to prepare the new generation for the tasks awaiting it through an education shaped on the entire human being, 103 I turned to Rudolf Steiner with the request to be taken into the Stuttgart School as teacher of natural science. 104 On this occasion I told him of my general scientific interests, and how I hoped to follow them up later on. 105 I spoke of my intended educational activity as something which might help me at the same time to prepare myself for this other task.

106 Anyone who learns so to see Nature that your ideas can be taken up and understood by the living, lively soul of the growing child will thereby be training the self, I thought, in just that kind of observation and thinking which the new science of Nature demands. 107 Rudolf Steiner agreed with this, and it was not long afterwards that I joined the school where I was to work for eleven years as a science master in the senior classes, which activity I have since continued outside Germany in a more or less similar form.

108 This conversation with Rudolf Steiner took place in a large hall where, while we were talking, over a thousand people were assembling to discuss matters of concern to the Anthroposophical Movement. 109 This did not prevent him from asking me about the details of my examination work, in which I was still engaged at that time; he always gave himself fully to whatever claimed his attention at the moment. 110 I told him of my experimental researches in electrical high-frequency phenomena, briefly introducing the particular problem with which I was occupied.

111 I took it for granted that a question from such a specialised branch of physics would not be of much interest to him. 112 Judge of my astonishment when he at once took out of his pocket a note-book and a huge carpenter's pencil, made a sketch and proceeded to speak of the problem as one fully conversant with it, 113 and in such a way that he gave me the starting point for an entirely new conception of electricity. 114 It was instantly borne in on me that if electricity came to be understood in this sense, results would follow which in the end would lead to a quite new technique in the use of it. 115 From that moment it became one of my life's aims to contribute whatever my circumstances and powers would allow to the development of an understanding of Nature of this kind.

116 The speaker was the late Dr. Elizabeth Vreede, for some years leader of the Mathematical-Astronomical Section at the Goetheanum, Dornach, Switzerland. 117 The activities mentioned above do not exhaust the practical possibilities of Spiritual Science. 118 At that time (1921) Rudolf Steiner had not yet given his indications for the treatment of children needing special care of soul and body, 119 or for the renewal of the art of acting, or for the conquest of materialistic methods in agricultural practice. 120 Nor did there yet exist the movement for religious renewal Which Dr. Fr. Rittelmeyer later founded, with the help and advice of Rudolf Steiner.

WHERE DO WE STAND TO-DAY?

Ernst Lehrs

2 In the year 1932, when the world celebrated the hundredth anniversary of Goethe's death, Professor W. Heisenberg, one of the foremost thinkers in the field of modern physics, delivered a speech before the Saxon Academy of Science 2 which may be regarded as symptomatic of the need in recent science to investigate critically the foundations of its own efforts to know Nature. 3 In this speech Heisenberg draws a picture of the progress of science which differs significantly from the one

generally known. 4 Instead of giving the usual description of this progress as 'a chain of brilliant and surprising discoveries', 5 he shows it as resting on the fact that, with the aim of continually simplifying and unifying the scientific conception of the world, human thinking, in course of time, has narrowed more and more the scope of its inquiries into outer Nature. 6 'Almost every scientific advance is bought at the cost of renunciation, almost every gain in knowledge sacrifices important standpoints and established modes of thought. 7 As facts and knowledge accumulate, the claim of the scientist to an understanding of the world in a certain sense diminishes.' 8 Our justifiable admiration for the success with which the unending multiplicity of natural occurrences on earth and in the stars has been reduced to so simple a scheme of laws-- 9 Heisenberg implies-- must therefore not make us forget that these attainments are bought at the price 'of renouncing the aim of bringing the phenomena of Nature to our thinking in an immediate and living way'.

10 In the course of his exposition, Heisenberg also speaks of Goethe, in whose scientific endeavours he perceives a noteworthy attempt to set scientific understanding upon a path other than that of progressive self-restriction. 11 'The renouncing of life and immediacy, which was the premise for the progress of natural science since Newton, formed the real basis for the bitter struggle which Goethe waged against the physical optics of Isaac Newton. 12 It would be superficial to dismiss this struggle as unimportant: there is much significance in one of the most outstanding people directing all of own efforts to fighting against the development of Newtonian optics.' 13 There is only one thing for which Heisenberg critises Goethe: 'If one should wish to reproach Goethe, it could only be for not going far enough-- 14 that is, for having attacked the views of Newton instead of declaring that the whole of Newtonian Physics-Optics, Mechanics and the Law of Gravitation - were from the devil.' 15 Although the full significance of Heisenberg's remarks on Goethe will become apparent only at a

later stage of our discussion, they have been quoted here because they form part of the symptom we wish to characterise. 16 Only this much may be pointed out immediately, that Goethe - if not in the scientific then indeed in the poetical part of his writings - did fulfilll what Heisenberg rightly feels to have been his true task.

17 We mentioned Heisenberg's speech as a symptom of a certain tendency, characteristic of the latest phase in science, to survey critically its own epistemological foundations. 18 A few years previous to Heisenberg's speech, the need of such a survey found an eloquent advocate in the late Professor A. N. Whitehead, in his book ‘Science and the Modern World’, 19 where, in view of the contradictory nature of modern physical theories, he insists that 'if science is not to degenerate into a medley of ad-hoc hypotheses, it must become philosophical and enter upon a thorough criticism of its own foundations'.

20 Among the scientists who have felt this need, and who have taken pains to fulfilll it, the late Professor A. Eddington obtains an eminent position. 21 Among his relevant utterances we will quote here the following, because it contains a concrete statement concerning the field of external observation which forms the basis for the modern scientific world-picture. 22 In his Philosophy of Physical Science we find him stating that 'ideally, all our knowledge of the universe could have been reached by visual sensation alone-- in fact by the simplest form of visual sensation, colourless and non-stereoscopic'. 23 In other words, in order to obtain scientific cognition of the physical world, human has felt constrained to surrender the use of all own senses except the sense of sight, and to limit even the act of seeing to the use of a single, colour-blind eye.

24 Let us listen to yet another voice from the ranks of present-day science, expressing a criticism which is symptomatic of our time. 25 It comes from the late physiologist, Professor A, Carrel, who, concerning the effect which scientific research has had on human's life in general, says in his book, Human the Unknown: 26

MATTER

'The sciences of inert matter have led us into a country that is not ours. ... Human is a stranger in the world you have created.'

27 Of these utterances, Eddington's is at the present point of our discussion of special interest for us; 28 for he outlines in it the precise field of sense-perception into which science has withdrawn in the course of that general retreat towards an ever more restricted questioning of Nature which was noted by Heisenberg.

29 The pertinence of Eddington's statement is shown immediately one considers what a person would know of the world if your only source of experience were the sense of sight, still further limited in the way Eddington describes. 30 Out of everything that the world brings to the totality of our senses, there remains nothing more than mere movements, with certain changes of rate, direction, and so on. 31 The picture of the world received by such an observer is a purely kinematic one. And this is, indeed, the character of the world-picture of modern physical science. 32 For in the scientific treatment of natural phenomena all the qualities brought to us by our other senses, such as colour, tone, warmth, density and even electricity and magnetism, are reduced to mere movement-changes.

33 As a result, modern science is prevented from conceiving any valid idea of 'force'. In so far as the concept 'force' appears in scientific considerations, it plays the part of an 'auxiliary concept', 34 and what human naively conceives as force has come to be defined as merely a 'descriptive law of behaviour'. 35 We must leave it for later considerations to show how the scientific mind of human has created for itself the conviction that the part of science occupied with the actions of force in Nature can properly be treated with purely kinematic concepts. 36 It is the fact itself which concerns us here. In respect of it, note as a characteristic of modern text-books that they often simply use the term 'kinetics' (a shortening of kinematics) to designate the science of 'dynamics'.

37 In the course of our investigations we shall discover the peculiarity in human nature

which - during the first phase, now ended, of human's struggle towards scientific awareness-- 38 has caused this renunciation of all sense-experiences except those which come to human through the sight of a single colour-blind eye. 39 It will then also become clear out of what historic necessity this self-restriction of scientific inquiry arose. 40 The acknowledgment of this necessity, however, must not prevent us from recognising the fact that, as a result of this restriction, modern scientific research, which has penetrated far into the dynamic substrata of Nature, 41 finds itself in the peculiar situation that it is not at all guided by its own concepts, but by the very forces it tries to detect. 42 And in this fact lies the root of the danger which besets the present age.

43 You who recognises this, therefore, feels impelled to look for a way which leads beyond a one-eyed, colour-blind conception of the world. 44 It is the aim of this book to show that such a way exists and how it can be followed. 45 Proof will thereby be given that along this way not only is a true understanding achieved of the forces already known to science-- though not really understood by it,-- 46 but also that other forces, just as active in Nature as for example electricity and magnetism, come within reach of scientific observation and understanding. 47 And it will be shown that these other forces are of a kind that requires to be known to-day if we are to restore the lost balance to human civilisation.

48 There is a rule known to physicians that 'a true diagnosis of a case contains in itself the therapy'. 49 No true diagnosis is possible, however, without investigation of the 'history' of the case. 50 Applied to our task, this means that we must try to find an aspect of human development, both individual and historical, 51 which will enable us to recognise in human's own being the cause responsible for the peculiar narrowing of the scope of scientific inquiry, as described by the scientists cited above.

52 A characteristic of scientific inquiry, distinguishing it from human's earlier ways of solving the riddles of the world, 53 is that

it admits as instruments of knowledge exclusively those activities of the human soul over which we have full control because they take place in the full light of consciousness. 54 This also explains why there has been no science, in the true sense of the word, prior to the beginning of the era commonly called 'modern'--that is, before the fifteenth century. 55 For the consciousness on which human's scientific striving is based is itself an outcome of human evolution. 56 This evolution, therefore, needs to be considered in such a way that we understand the origin of modern human's state of mind, 57 and in particular why this state of mind cannot of itself have any other relationship to the world than that of a spectator. 58 For let us be clear that this peculiar relationship by no means belongs only to the scientifically engaged mind. 59 Every adult in our age is, by virtue of your psycho-physical structure, more or less a world-spectator. 60 What distinguishes the state of human's mind when engaged in scientific observation is that it is restricted to a one-eyed colour-blind approach.

61 'Death is the price human has to pay for own brain and own personality'-- 62 this is how a modern physiologist (A. Carrel in his aforementioned book, Human the Unknown) describes the connexion between human's bodily functions and your waking consciousness. 63 It is characteristic of the outlook prevailing in the nineteenth century that thinking was regarded as the result of the life of the body; that is, of the body's matter-building processes. 64 Hence no attention was paid at that time to the lonely voice of the German philosopher, C. Fortlage (1806-81), who in his System of Psychology as Empirical Science suggested that consciousness is really based on death processes in the body. 65 From this fact he boldly drew the conclusion (known to us today to be true) that if 'partial death' gave rise to ordinary consciousness, then 'total death' must result in an extraordinary enhancement of consciousness.

66 Again, when in our century Rudolf Steiner drew attention to the same fact, which he had found

along his own lines of investigation, 67 showing thereby the true role of the nervous system in regard to the various activities of the soul, official science turned a deaf ear to his pronouncement. 68 To-day the scientist regards it as forming part of 'unknown human' that life must recede-- in other words, that the organ-building processes of the body must come to a standstill-- if consciousness is to come into its own.

69 With the recognition of a death process in the nervous system as the bodily foundation of consciousness, and particularly of human's conceptual activities, 70 the question arises as to the nature of those activities which have their foundation in other systems, such as that of the muscles, where life, not death, prevails. 71 Here an answer must be given which will surprise the reader acquainted with modern theories of psycho-physical interaction; but if you meets it with an open mind you will not find it difficult to test.

72 Just as the conceptual activity has as its bodily foundation the brain, with the nervous appendages, 73 so it is volitional activity which is based on processes taking place in the muscular region of the body and in those organs which provide the body's metabolism.

74 A statement which says that human's will is as directly based on the metabolic processes of the body, both inside and outside the muscles, as is your perceiving and thought-forming mind on a process in the nerves, is bound to cause surprise. 75 Firstly, it seems to leave out the role commonly ascribed to the so-called motoric part of the nervous system in bringing about bodily action; 76 and secondly, the acknowledgment of the dependence of consciousness on corporeal 'dying' implies that willing is an unconscious activity because of its being based on life processes of the body.

77 The first of these two problems will find its answer at a later stage of our discussion when we shall see what entitles us to draw a direct connexion between volition and muscular action. 78 To answer the second problem, simple self-observation is required. This tells us that, when we move a limb, all

that we know of is the intention-- in its conceptual form-- which rouses the will and gives it its direction, and the fact of the completed deed. 79 In between, we accompany the movement with a dim awareness of the momentary positions of the parts of the body involved, so that we know whether or not they are moving in the intended manner.

80 This awareness is due to a particular sense, the 'sense of movement' or 'muscular sense' - one of those senses whose existence physiology has lately come to acknowledge. 81 Nothing, however, is known to us of all the complex changes which are set into play within the muscles themselves in order to carry out some intended movement. And it is these that are the direct outcome of the activity of our will.

82 Regarding human's psycho-physical organisation thus, we come to see in it a kind of polarity-- 83 a death-pole, as it were, represented by the nerves including their extension into the senses, and a life-pole, represented by the metabolic and muscular systems; 84 and connected with them a pole of consciousness and one of unconsciousness-- or as we can also say, of waking and sleeping consciousness. 85 For the degree of consciousness on the side of the life-pole is not different from the state in which the entire human being dwells during sleep.

86 It is by thus recognising the dependence of consciousness on processes of bodily disintegration that we first come to understand why consciousness, once it has reached a certain degree of brightness, is bound to suffer repeated interruptions. 87 Every night, when we sleep, our nervous system becomes alive-- though with gradually decreasing intensity-- in order that what has been destroyed during the day may be restored. 88 While the system is kept in this condition, no consciousness can obtain in it.

89 In between the two polarically opposite systems there is a third, again of clearly distinct character, which functions as a mediator between the two. 90 Here all processes are of a strictly rhythmic nature, as is shown by the process of breathing and the pulsation of the blood. 91 This system, too,

provides the foundation for a certain type of psychological process, namely feeling. 92 That feeling is an activity of the soul distinct from both thinking and willing, and that it has its direct counterpart in the rhythmic processes of the body, can be most easily tested through observing oneself when listening to music.

93 As one might expect from its median position, the feeling sphere of the soul is characterised by a degree of consciousness half-way between waking and sleeping. 94 Of our feelings we are not more conscious than of our dreams; we are as little detached from them as from our dream experiences while these last; 95 what remains in our memory of past feelings is usually not more than what we remember of past dreams.

96 This picture of the threefold psycho-physical structure of human will now enable us to understand the evolution of consciousness both in individual life and in the life of humankind. 97 To furnish the foundation of waking consciousness, parts of the body must become divorced from life. 98 This process, however, is one which, if we take the word in its widest sense, we may call, ageing. 99 All organic bodies, and equally that of human, are originally traversed throughout by life. 100 Only gradually certain parts of such an organism become precipitated, as it were, from the general organic structure, and they do so increasingly towards the end of that organism's life-span. 101 In the human body this separation sets in gently during the later stages of embryonic development and brings about the first degree of independence of bones and nerves from the rest of the organism. 102 The retreat of life continues after birth, reaching a certain climax in the nervous system at about the twenty-first year. 103 In the body of a small child there is still comparatively little contrast between living and non-living organs. 104 There is equally little contrast between sleeping and waking condition in its soul. And the nature of the soul at this stage is volition throughout. 105 Never, in fact, does human's soul so intensively will as in the time when it is occupied in bringing the body into an upright position, 106

and never again does it exert its strength with the same unconsciousness of the goal to which it strives. 107 What, then, is the soul's characteristic relationship to the world around at this stage? The following observations will enable us to answer this question.

108 It is well known that small children often angrily strike an object against which they have stumbled. 109 This has been interpreted as 'animism', by which it is meant that the child, by analogy with own experience of the self as a soul-filled body, imagines the things in own surroundings to be similarly ensouled. 110 Anyone who really observes the child's mode of experience-- of which we as adults, indeed, keep something in our will-life-- is led to a quite different interpretation of such a phenomenon. 111 For you realises that the child neither experiences the self as soul-entity distinct from own body, nor faces the content of the world in so detached a manner as to be in need of using own imagination to read into it any soul-entities distinct from one’s own.

112 In this early period of your life the human being still feels the world as part of the self, and the self as part of the world. 113 Consequently, your relation to the objects around you and to your own body is one and the same. 114 To the example of the child beating the external object it has stumbled against, there belongs the complementary picture of the child who beats the self because it has done something which makes the self angry with the self.

115 In sharp contrast to this state of oneness of the child's soul, in regard both to its own body and to the surrounding world, there stands the separatedness of the adult's intellectual consciousness, severed from both body and world. 116 What happens to this part of the soul during its transition from one condition to the other may be aptly described by using a comparison from another sphere of natural phenomena. 117 Later descriptions in this book will show that a comparison such as the one used here is more than a mere external analogy.

MATTER

118 Let us think of water in which salt has been dissolved. In this state the salt is one with its solvent; there is no visible distinction between them. The situation changes when part of the salt crystallises. 119 By this process the part of the salt substance concerned loses its connexion with the liquid and contracts into individually outlined and spatially defined pieces of solid matter. It thereby becomes optically distinguishable from its environment.

120 Something similar happens to the soul within the region of the nervous system. What keeps the soul in a state of unconsciousness as long as the body, in childhood, is traversed by life throughout, 121 and what continues to keep it in this condition in the parts which remain alive after the separation of the nerves, is the fact that in these parts - to maintain the analogy - the soul is dissolved in the body. 122 With the growing independence of the nerves, the soul itself gains independence from the body. 123 At the same time it undergoes a process similar to contraction whereby it becomes discernible to itself as an entity distinguished from the surrounding world. 124 In this way the soul is enabled, eventually, to meet the world from outside as a self-conscious onlooker.

125 What we have here described as the emergence of an individual's intellectual consciousness from the original, purely volitional condition of the soul is nothing but a replica of a greater process 126 through which humankind as a whole, or more exactly Western humankind, has gone in the course of its historical development. 127 Human was not always the 'brain-thinker' you are to-day. 128 Directly the separation of the nerve system was completed, and thereby the full clarity of the brain-bound consciousness achieved, human began to concern the self with science in the modern sense.

129 To understand why this science became restricted to one-eyed, colour-blind observation we need only apply to the human sense system, in particular, what we have learn't concerning human's threefold being.

130 Sharply distinguished by their respective modes of functioning though they are, the three bodily systems are each spread out through the whole body and are thus to be found everywhere adjacent to each other. 131 Hence, the corresponding three states of consciousness, the sleeping, dreaming and waking, are also everywhere adjacent and woven into one another. 132 It is the predominance of one or other which imparts a particular quality of soul to one or other region of the body. 133 This is clearly shown within the realm of sense activity, itself the most conscious part of the human being. 134 It is sufficient to compare, say, the senses of sight and smell, and to notice in what different degree we are conscious of the impressions they convey, and how differently the corresponding elements of conception, feeling and willing are blended in each. 135 We never turn away as instinctively from objectionable colour arrangement as from an unpleasant smell. 136 How small a part, on the other hand, do the representations of odours play in our recollection of past experiences, compared with those of sight. The same is valid in descending measure for all other senses.

137 Of all senses, the sense of sight has in greatest measure the qualities of a 'conceptual sense'. 138 The experiences which it brings, and these alone, were suitable as a basis for the new science, and even so a further limitation was necessary. 139 For in spite of the special quality of the sense of sight, it is still not free from certain elements of feeling and will - that is, from elements with the character of dream or sleep. 140 The first plays a part in our perception of colour; the second, in observing the forms and perspective ordering of objects we look at.

141 Here is repeated in a special way the threefold organisation of human, for the seeing of colour depends on an organic process apart from the nerve processes and similar to that which takes place between heart and lungs, 142 whilst the seeing of forms and spatial vision depend upon certain movements of the eyeball-- 143 quick traversing of the outline of

the viewed object with the line of sight, alteration of the angle between the two axes of sight according to distance,-- 144 in which the eye is active as a sort of outer limb of the body, an activity which enters our consciousness as little as does that of our limbs. 145 It now becomes clear that no world-content obtained in such more or less unconscious ways could be made available for the building of a new scientific world-conception. 146 Only as much as human experiences through the sight of a single, colour-blind eye, could be used.

147 If we would understand the role of science in the present phase of human development, we must be ready to apply two entirely different and seemingly contradictory judgments to one and the same historical phenomenon. 148 The fact that something has occurred out of historical necessity-- that is, a necessity springing from the very laws of cosmic evolution-- does not save it from having a character which, in view of its consequences, must needs be called tragic. 149 In this era of advanced intellectualism, little understanding of the existence of true tragedy in human existence has survived. 150 As a result, the word 'tragedy' itself has deteriorated in its meaning and is nowadays used mostly as a synonym for 'sad event', 'calamity' 'serious event', even 'crime' (Oxford Diet.). 151 In its original meaning, however, springing from the dramatic poetry of ancient Greece, the word combines the concept of calamity with that of inevitability; 152 the author of the destructive action was not held to be personally responsible for it, since He was caught up in a nexus of circumstances which He could not change.

153 This is not the place to discuss why tragedy in this sense forms part of human's existence. It suffices to acknowledge that it does and, where it occurs, to observe it with scientific objectivity.

154 Our considerations, starting from certain statements made by some leading scientific thinkers of our time, have helped us not only to confirm the truth inherent in these statements, 155 but to

recognise the facts stated by them as being the outcome of certain laws of evolution and thereby having an historic necessity. 156 This, however, does not mean that human's scientific labours, carried out under the historically given restrictions, great and successful as these labours were and are, have not led to calamitous effects such as we found indicated by Professor Carrel. 157 The sciences of matter have led human into a country that is not yours, and the world which you have created by means of scientific research is not only one in which you are a stranger but one which threatens to-day to deprive you of your own existence. 158 The reason is that this world is essentially a world of active forces, and the true nature of these is something which modern human, restricted to your onlooker-consciousness, is positively unable to conceive.

159 We have taken a first step in diagnosing human's present spiritual condition. A few more steps are required to lead us to the point where we can conceive the therapy you needs.

160 This address and another by the same author are published together under the common title, Wandlungen in den Grundlagen der Naturwissenschaft ('Changes in the foundations of Natural Science'). 161 Heisenberg's name has become known above all by his formulation of the so-called Principle of Indeterminacy.

162 See, in this respect, Faust's dispute with Mephistopheles on the causes responsible for the geological changes of the earth. (Faust II, Act 4)

163 See also Eddington's more elaborate description of this fact in his ‘New Pathways in Science’.

164 The above statement, like others of Eddington's, has been Contested from the side of professional philosophy as logically untenable. Our own further discussion will show that it accords with the facts.

165 Both words, kinematics and kinetics, are derivatives of the Greek word kinein, to move. 166 The term 'kinematic' is used when motion is considered abstractly without reference to force or mass. Kinetics is applied kinematics, or,

as pointed out above, dynamics treated with kinematic concepts.

167 These last statements will find further illustration in the next two chapters.

168 First published in 1917 in his book Von SeelenrÃ¤tseln. Homer's people still think with the diaphragm (phrenes). 169 Similarly, the ancient practice of Yoga, as a means of acquiring knowledge, shows that at the time When it flourished human's conceptual activity was felt to be seated elsewhere than in the head.

170 This must not be confused with the fact that a smell may evoke other memories by way of association.

171 For one who endeavours to observe historical facts in the manner here described, it is no mere play of chance that the father of scientific atomism, John Dalton, was by nature colour blind. 172 In fact, colour blindness was known, for a considerable time during the last century, as 'Daltonism', since it was through the publication of Dalton's self-observations that for the first time general attention was drawn to this phenomenon.

THE ONLOOKER'S PHILOSOPHIC MALADY

Ernst Lehrs

3 In your isolation as world spectator, the modern philosopher was bound to reach two completely opposite views regarding the objective value of human thought. 2 One of these was given expression in Descartes' famous words: Cogito ergo sum ('I think, therefore I am'). 3 Descartes (1596-1650), rightly described as the inaugurator of modern philosophy, thus held the view that only in his own thought-activity does human find a guarantee of his own existence. 4 In coming to this view, Descartes took as his starting-point his experience that human consciousness contains only the thought pictures evoked by sense-perception, and yet knows nothing of the how and why of the things responsible for such impressions. 5 He thus found himself compelled, in the first place, to doubt whether any of these things had any objective existence, at all. 6 Hence, there remained over for him only one indubitable item in the entire

content of the universe – his own thinking; for were he to doubt even this, he could do so only by again making use of it. 7 From the 'I doubt, therefore I am', he was led in this way to the 'I think, therefore I am'.

8 The other conception of human thought reached by the onlooker-consciousness was diametrically opposed to that of Descartes, and entirely cancelled its conceptual significance. 9 It was put forward - not long afterwards - by Robert Hooke (1635-1703), the first scientist to make systematic use of the newly invented microscope by means of which he made the fundamental discovery of the cellular structure of plant tissues. 10 It was, indeed, on the strength of his microscopic studies that he boldly undertook to determine the relationship of human thought to objective reality. 11 He published his views in the introduction to his Micrographia, the great work in which, with the lavish help of carefully executed copper engravings, he made his microscopic observations known to the world.

12 Hooke's line of thought is briefly as follows: In past ages humans subscribed to the naive belief that what they have in their consciousness as thought pictures of the world, actually reproduces the real content of that world. 13 The microscope now demonstrates, however, how much the familiar appearance of the world depends on the structure of our sense apparatus; 14 for it reveals a realm just as real as that already known to us, but hitherto concealed from us because it is not accessible to the natural senses. 15 Accordingly, if the microscope can penetrate through the veil of illusion which normally hides a whole world of potentially visible phenomena, 16 it may be that it can even teach us something about the ideas we have hitherto formed concerning the nature of things. 17 Perhaps it can bring us a step nearer the truth in the sphere of thought, as it so obviously has done in that of observation.

18 Of all the ideas that human reason can form, Hooke considered the simplest and the most fundamental to be the geometrical concepts of point and

straight line. 19 Undoubtedly we are able to think these, but the naÃ¯ve consciousness takes for granted that it also perceives them as objective realities outside itself, so that thoughts and facts correspond to each other. 20 We must now ask, however, if this belief is not due to an optical deception. Let us turn to the microscope and see what point and line in the external world look like through it.

21 For his investigation Hooke chose the point of a needle and a knife-edge, as providing the best representatives among physical objects of point and straight line. 22 In the sketches produced we may see how Hooke made clear to his readers how little these two things, when observed through the microscope, resemble what is seen by the unaided eye. 23 This fact convinced Hooke that the apparent agreement between the world of perception and the world of ideas rests on nothing more solid than an optical limitation (Plate I).

24 Compared with the more refined methods of present-day thought, Hooke's procedure may strike us as somewhat primitive. 25 Actually he did nothing more than has since been done times without number; for the scientist has become more and more willing to allow artificially evoked sense-perceptions to dictate the thoughts he uses in forming a scientific picture of the world.

26 In the present context we are concerned with the historical import of Hooke's procedure. 27 This lies in the fact that, immediately after Descartes had satisfied himself that in thinking human had the one sure guarantee of own existence, Hooke proved in a seemingly indubitable manner that thinking was entirely divorced from reality. 28 It required only another century for philosophy to draw from this the unavoidable consequence. 29 It appeared in the form of Hume's philosophic system, the outcome of which was universal scepticism. 30 As we shall see in due course, Hume's mode of reasoning continues to rule scientific thought even to-day, 31 quite irrespective of the fact that science itself claims to have its philosophical parent in Kant, the very thinker who devoted his life's work to the refutation of Hume.

32 On the basis of his investigations into human consciousness Hume felt obliged to reason thus: My consciousness, as I know it, has no contact with the external world other than that of a mere outside onlooker. 33 What it wins for its own content from the outer world is in the nature of single, mutually unrelated parts. 34 Whatever may unite these parts into an objective whole within the world itself can never enter my consciousness; 35 and any such unifying factor entertained by my thought can be only a self-constructed, hypothetical picture. 36 Hume summed up his view in two axioms which he himself described as the alpha and omega of his whole philosophy. 37 The first runs: 'All our distinct perceptions are distinct existences.' The other: 'The Mind never perceives any real connexions between distinct existences.' (Treatise of Human Nature.)

38 If once we agree that we can know of nothing but unrelated thought pictures, because our consciousness is not in a position to relate these pictures to a unifying reality, 39 then we have no right to ascribe, with Descartes and his school, an objective reality to the self. 40 Even though the self may appear to us as the unifying agent among our thoughts, it must itself be a mental picture among mental pictures; and human can have no knowledge of any permanent reality outside this fluctuating picture-realm. 41 So, with Hume, the onlooker-consciousness came to experience its own utter inability to achieve a knowledge of the objective existence either of a material world be-- behind all external phenomena, or of a spiritual self behind all the details of its own internal content. 42 Accordingly, human consciousness found itself hurled into the abyss of universal scepticism. 43 Hume himself suffered unspeakably under the impact of what he considered inescapable ideas-- rightly described from another side as the 'suicide of human intelligence'-- 44 and his philosophy often seemed to him like a malady, as he himself called it, against whose grip he could see no remedy. 45 The only thing left to him, if he was to

prevent philosophical suicide from ending in physical suicide, was to forget in daily life his own conclusions as far as possible.

46 What Hume experienced as his philosophical malady, however, was the result not of a mental abnormality peculiar to himself, but of that modern form of consciousness which still prevails in general today. 47 This explains why, despite all attempts to disprove Hume's philosophy, scientific thought has not broken away from its alpha and omega in the slightest degree.

48 A proof of this is to be found, for example, in the principle of Indeterminacy which has arisen in modern physics. 49 The conception of Indeterminacy as an unavoidable consequence of the latest phase of physical research is due to Professor W. Heisenberg. 50 Originally this conception forced itself upon Heisenberg as a result of experimental research. In the meantime the same idea has received its purely philosophical foundation. We shall here deal with both lines of approach.

51 After the discovery by Galileo of the parallelogram of forces, it became the object of classical physics-- unexpressed, indeed, until Newton wrote his 'Principia'-- 52 to bring the unchanging laws ruling Nature into the light of human consciousness, and to give them conceptual expression in the language of mathematical formulae. 53 Since, however, science was obliged to restrict itself to what could be observed with a single, colour-blind eye, 54 physics has taken as its main object of research the spatio-temporal relationships, and their changes, between discrete, ideally conceived, point-like particles. 55 Accordingly, the mathematically formulable laws holding sway in Nature came to mean the laws according to which the smallest particles in the material foundation of the world change their position with regard to each other. 56 A science of this kind could logically maintain that, if ever it succeeded in defining both the position and the state of motion, in one single moment, of the totality of particles composing the universe, it would have discovered the law on which universal existence depends. 57

This necessarily rested on the presupposition that it really was the ultimate particles of the physical world which were under observation. 58 In the search for these, guided chiefly by the study of electricity, the physicists tracked down ever smaller and smaller units; and along this path scientific research has arrived at the following peculiar situation.

59 To observe any object in the sense world we need an appropriate medium of observation. 60 For ordinary things, light provides this. In the sense in which light is understood to-day, this is possible because the spatial extension of the single light impulses, their so-called wavelength, is immeasurably smaller than the average magnitude of all microscopically visible objects. 61 This ensures that they can be observed clearly by the human eye. 62 Much smaller objects, however, will require a correspondingly shorter wave-length in the medium of observation. 63 Now shorter wave-lengths than those of visible light have been found in ultra-violet light and in X-rays; and these, accordingly, are now often used for minute physical research.

64 In this way, however, we are led by Nature to a definite boundary; for we now find ourselves in a realm where the dimensions of the observation medium and the observed object are more or less the same. 65 The result, unfortunately, is that when the 'light' meets the object, it changes the latter's condition of movement.

66 On the other hand, if a 'light' is used whose wave-length is too big to have any influence on the object's condition of movement, it precludes any exact determination of the object's location.

67 Thus, having arrived at the very ground of the world-- that is, where the cosmic laws might be expected to reveal themselves directly-- 68 the scientist finds the self in the remarkable situation of only being able to determine accurately either the position of an observed object and not its state of motion, or its state of motion and not its position. 69 The law you seeks, however, requires that both should be known at the same time.

70 Nor is this situation due to the imperfection of the scientific

apparatus employed, but to its very perfection, 71 so that it appears to arise from the nature of the foundation of the world-- in so far, at least, as modern science is bound to conceive it.

72 If it is true that a valid scientific knowledge of Nature is possible only in the sphere open to a single-eyed, colour-blind observation, 73 and if it is true-- as a science of this kind, at any rate, is obliged to believe-- that all processes within the material foundation of the world depend on nothing but the movements of certain elementary particles of extremely small size, 74 then the fact must be faced that the very nature of these processes rules out the discovery of any stable ordering of things in the sense of mathematically formulable laws. 75 The discovery of such laws will then always be the last step but one in scientific investigation; the last will inevitably be the dissolution of such laws into chaos. 76 For a consistent scientific thinking that goes this way, therefore, nothing is left but to recognise chaos as the only real basis of an apparently ordered world, 77 a chaos on whose surface the laws that seem to hold sway are only the illusory picturings of the human mind. 78 This, then, is the principle of Indeterminacy as it has been encountered in the course of practical investigation into the electrical processes within physical matter.

79 In the following way Professor SchrÃ¶dinger, another leading thinker among modern theoretical physicists, explains the philosophical basis for the principle of Indeterminacy, which scientists have established in the meantime: 80 'Every quantitative observation, every observation making use of measurement, is by nature discontinuous... 81 However far we go in the pursuit of accuracy we shall never get anything other than a finite series of discrete results... 82 The raw material of our quantitative cognition of nature will always have this primitive and discontinuous character... 83 It is possible that a physical system might be so simple that this meagre information would suffice to settle its fate; in that case Nature would not be more complicated

than a game of chess. 84 To determine a position of a game of chess thirty-three facts suffice… If Nature is more complicated than a game of chess, a belief to which one tends to incline, then a physical system cannot be determined by a finite number of observations. 85 But in practice a finite number of observations is all that we could make.'

86 Classical physics, the author goes on to show, held that it was possible to gain a real insight into the laws of the universe, 87 because in principle an infinite number of such discrete observations would enable us to fill in the gaps sufficiently to allow us to determine the system of the physical world. 88 Against this assumption modern physics must hold the view that an infinite number of observations cannot in any case be carried out in practice, 89 and that nothing compels us to assume that even this would suffice to furnish us with the means for a complete determination, which alone would allow us to speak of 'law' in Nature. 90 'This is the direction in which modern physics has led us without really intending it.'

91 What we have previously said will make it clear enough that in these words of a modern physicist we meet once more the two fundamentals of Hume's philosophy. 92 It is just as obvious, however, that the very principle thus re-affirmed at the latest stage of modern physical science was already firmly established by Hooke, when he sought to prove to his contemporaries the unreality of human ideas.

93 Let us recall Hooke's motives and results. The human reason discovers that certain law-abiding forms of thought dwell within itself; these are the rules of mathematical thinking. 94 The eye informs the reason that the same kind of law and order is present also in the outer world. 95 The mind can think point and line; the eye reports that the same forms exist in Nature outside. 96 The reason mistrusts the eye, however, and with the help of the microscope 'improves' on it. 97 What hitherto had been taken for a compact, regulated whole now collapses into a heap of unordered

parts; 98 behind the illusion of law a finer observation detects the reality of chaos!

99 Had science in its vehement career from discovery to discovery not forgotten its own beginnings so completely, it would not have needed its latest researches to bring out a principle which it had in fact been following from the outset-- 100 a principle which philosophy had already recognised, if not in quite the same formulation, in the eighteenth century. 101 Indeterminacy, as we have just seen it explained by SchrÃ¶dinger, is nothing but the exact continuation of Humean scepticism. In his book, Science and the Human Temperament (Dublin, 1935).

THE COUNTRY THAT IS NOT OURS

Ernst Lehrs

4 The last two chapters have served to show the impasse into which human perception and thinking have come-- 2 in so far as they have been used for scientific purposes-- by virtue of the relationship to the world in which human's consciousness found itself when it awoke to itself at the beginning of modern times. 3 Now although the onlooker in human, especially in the earliest stage of our period, gave itself up to the conviction that a self-contained picture of the universe could be formed out of the kind of materials available to it, 4 it nevertheless had a dim inkling that this picture, because it lacked all dynamic content, had no bearing on the real nature of the universe. 5 Unable to find this reality within the self, the world-onlooker set about searching in own way for what was missing, and turned to the perceptible world outside human. 6 Here you came, all unexpectedly, upon ... electricity. Scarcely was electricity discovered than it drew human scientific thinking irresistibly into its own realm. 7 Thereby human found the self, with a consciousness completely blind to dynamics, within a sphere of only too real dynamic forces. 8 The following description will show what results this has had for human and own civilisation.

9 First, let us recall how potent a role electricity has come to play in

social life through the great discoveries which began at the end of the eighteenth century. 10 To do this we need only compare the present relationship between production and consumption in the economic sphere with what it was before the power-machine, and especially the electrically driven machine, had been invented. 11 Consider some major public undertaking in former times-- say the construction of a great mediaeval cathedral. Almost all the work was done by human beings, with some help, of course, from domesticated animals. 12 Under these circumstances the entire source of productive power lay in the will-energies of living beings, whose bodies had to be supplied with food, clothing and housing; 13 and to provide these, other productive powers of a similar kind were required near the same place. 14 Accordingly, since each of the power units employed in the work was simultaneously both producer and consumer, a certain natural limit was placed on the accumulation of productive forces in any one locality. 15 This condition of natural balance between production and consumption was profoundly disturbed by the introduction of the steam engine; 16 but even so there were still some limits, though of a quite different kind, to local concentrations of productive power. 17 For steam engines require water and coal at the scene of action, and these take up space and need continual shifting and replenishing. 18 Owing to the very nature of physical matter, it cannot be heaped up where it is required in unlimited quantities.

19 All this changed directly human succeeded in producing energy electro-magnetically by the mere rotation of material masses, 20 and in using the water-power of the earth-- itself ultimately derived from the cosmic energies of the sun-- for driving own dynamos. 21 Not only is the source of energy thus tapped practically inexhaustible, but the machines produce it without consuming on their own account, 22 apart from wear and tear, and so make possible the almost limitless accumulation of power in one place. 23 For electricity is

distinguished from all other power-supplying natural forces, living or otherwise, 24 precisely in this, that it can be concentrated spatially with the aid of a physical carrier whose material bulk is insignificant compared with the energy supplied.

25 Through this property of electricity it has been possible for human to extend the range of own activity in all directions, far and near. 26 So the balance between production and consumption, which in previous ages was more or less adequately maintained by natural conditions, has been entirely destroyed, and a major social-economic problem created.

27 In yet another way, and through quite another of its properties, electricity plays an important part in modern life. 28 Not only does it compete with the human will; it also makes possible automatically intelligent operations quite beyond anything human can do on your own. 29 There are innumerable examples of this in modern electrical technology; we need mention here only the photo-electric cell and the many devices into which it enters.

30 To an ever-increasing, quite uncontrolled degree-- for to the mind of present-day human it is only natural to translate every new discovery into practice as soon and as extensively as possible-- electricity enters decisively into our modern existence. 31 If we take all its activities into account, we see arising amongst humanity a vast realm of labour units, possessed in their own way not only of will but of the sharpest imaginable intelligence. 32 Although they are wholly remote from human's own nature, you more and more subdues your thoughts and actions to theirs, allowing them to take rank as guides and shapers of your civilisation.

33 Turning to the sphere of scientific research, we find electricity playing a role in the development of modern thinking remarkably similar to its part as a labour-force in everyday life. 34 We find it associated with phenomena which, in Professor Heisenberg's words, expose their mutual connexions to exact mathematical thinking more readily than do any other facts of

Nature; 35 and yet the way in which these phenomena have become known has played fast and loose with mathematical thinking to an unparalleled degree. 36 To recognise that in this sphere modern science owes its triumphs to a strange and often paradoxical mixture of outer accident and error in human thought, we need only review the history of the subject without prejudice.

37 The discovery of electricity has so far been accomplished in four clearly distinct stages. The first extends from the time when humans first knew of electrical phenomena to the beginning of the natural scientific age; 38 the second includes the seventeenth and the greater part of the eighteenth centuries; 39 the third begins with Galvani's discovery and closes with the first observations of radiant electricity; and the fourth brings us to our own day. 40 We shall here concern ourselves with a few outstanding features of each phase, enough to characterise the strange path along which human has been led by the discovery of electricity.

41 Until the beginning of modern times, nothing more was known about electricity, or of its sister force, magnetism, than what we find in Pliny's writings. 42 There, without recognising a qualitative distinction between them, he refers to the faculty of rubbed amber and of certain pieces of iron to attract other small pieces of matter. 43 It required the awakening of that overruling interest in material Nature, characteristic of our own age, for the essential difference between electric and magnetic attraction to be recognised. 44 The first to give a proper description of this was Queen Elizabeth's doctor, Gilbert. His discovery was soon followed by the construction of the first electrical machine by the German Guericke-- 45 also known through his invention of the air pump-- which opened the way for the discovery that electricity could be transmitted from one place to another.

46 It was not, however, until the beginning of the eighteenth century that the crop of electrical discoveries began to increase considerably: 47 among these was the recognition of the dual nature

of electricity, by the Frenchman, Dufais, and the chance invention of the Leyden jar-- made simultaneously by the German, von Kleist, and two Dutchmen, Musschenbroek and Cunaeus. 48 The Leyden jar brought electrical effects of quite unexpected intensity within reach. 49 Stimulated by what could be done with electricity in this form, more and more people now busied themselves in experimenting with so fascinating a force of Nature, 50 until in the second third of the century a whole army of observers was at work, whether by way of profession or of hobby, finding out ever new manifestations of its powers.

51 The mood that prevailed in those days among people engaged in electrical research is well reflected in a letter written by the Englishman, Walsh, after he had established the electric nature of the shocks given by certain fishes, 52 to Benjamin Franklin, who shortly before had discovered the natural occurrence of electricity in the atmosphere: 53 'I rejoice in addressing these communications to You. You, who predicted and shewed that electricity wings the formidable bolt of the Atmosphere, will hear with attention that in the deep it speeds a humbler bolt, silent and invisible; 54 You, who analysed the electrical Phial, will hear with pleasure that its laws prevail in animate Phials; 55 You, who by Reason became an electrician, will hear with reverence of an instinctive electrician, gifted in your birth with a wonderful apparatus, and with the skill to use it.' (Phil. Trans. 1773.)

56 Dare one believe that in electricity the soul of Nature had been discovered? 57 This was the question which at that time stirred the hearts of very many in Europe. 58 Doctors had already sought to arouse new vitality in their patients by the use of strong electric shocks; attempts had even been made to bring the dead back to life by such means. 59 In a time like ours, when we are primarily concerned with the practical application of scientific discoveries, 60 we are mostly accustomed to regard such flights of thought from a past age as nothing but the unessential

accompaniment of youthful, immature science, and to smile at them accordingly as historical curiosities. 61 This is a mistake, for we then overlook how within them was hidden an inkling of the truth, however wrongly conceived at the time, 62 and we ignore the role which such apparently fantastic hopes have played in connexion with the entry of electricity into human civilisation. 63 Nor are such hopes confined to the eighteenth century; as we shall see, the same impulse urged Crookes a hundred years later to that decisive discovery which was to usher in the latest phase in the history of science, 64 a phase in which the investigating human spirit has been led to that boundary of the physical-material world where the transition takes place from inert matter into freely working energy.

64 If there was any doubt left as to whether in Nature the same power was at work which, in animal and human, was hidden away within the soul, this doubt seemed finally to have been dispelled through Galvani's discovery 65 that animal limbs could be made to move electrically through being touched by two bits of different metals. 66 No wonder that 'the storm which was loosed in the world of the physicists, the physiologists and the doctors through Galvani's publication can only be compared with the one crossing the political horizon of Europe at the same time. 67 Wherever there happened to be frogs and two pieces of different metals available, everyone sought proof with own eyes that the severed limbs could be marvellously re-enlivened.'

68 Like many of his contemporaries, Galvani was drawn by the fascinating behaviour of the new force of Nature to carry on electrical experiments as a hobby alongside his professional work, anatomical research. 69 For his experiments he used the room where his anatomical specimens were set out. So it happened that his electrical machine stood near some frogs' legs, prepared for dissection. 70 By a further coincidence his assistant, while playing with the machine, released a few sparks 71 just when some of the specimens were in such contact with the

surface beneath them that they were bound to react to the sudden alteration of the electric field round the machine caused by its discharge. At each spark the frogs' legs twitched. 72 What Galvani saw with his own eyes seemed to be no less than the union of two phenomena, one observed by Franklin in the heights of the atmosphere, the other by Walsh in the depths of the sea.

73 Galvani, as he himself describes, proceeded with immense enthusiasm to investigate systematically what accident had thus put into his hands. 74 He wanted first to see whether changes occurring naturally in the electrical condition of the atmosphere would call forth the same reaction in his specimens. 75 For this purpose he fastened one end of an iron wire to a point high up outside his house; 76 the lower end he connected with the nervous substance of a limb from one of his specimens, and to the foot of this he attached a second wire whose other end he submerged in a well. 77 The specimen itself was either enclosed in a glass flask in order to insulate it, or simply left lying on a table near the well. 78 And all this he did whenever a thunderstorm was threatening. As he himself reported: 'All took place as expected. 79 Whenever the lightning flashed, all the muscles simultaneously came into repeated and violent twitchings, so that the movements of the muscles, like the flash of the lightning, always preceded the thunder, 80 and thus, as it were, heralded its coming.' We can have some idea of what went on in Galvani's mind during these experiments 81 if we picture vividly to ourselves the animal limbs twitching about every time the lightning flashed, as if a revitalising force of will had suddenly taken possession of them.

82 In the course of his investigations-- he carried them on for a long time-- 83 Galvani was astonished to observe that some of his specimens, which he had hung on to an iron railing by means of brass hooks, sometimes fell to twitching even when the sky was quite clear and there was no sign of thunder. 84 His natural conclusion was that this must be

due to hitherto unnoticed electrical changes in the atmosphere. 85 Observations maintained for hours every day, however, led to no conclusive result; when twitchings did occur it was only with some of the specimens, and even then there was no discoverable cause. 86 Then it happened one day that Galvani, 'tired out with fruitless watching', took hold of one of the brass hooks by which the specimens were hung, and pressed it more strongly than usual against the iron railing. 87 Immediately a twitching took place. 'I was almost at the point of ascribing the occurrence to atmospheric electricity,'

88 Galvani tells us. All the same he took one of the specimens, a frog, into his laboratory and there subjected it to similar conditions by putting it on an iron plate, and pressing against this with the hook that was stuck through its spinal cord. 89 Immediately the twitching occurred again. He tried with other metals and, for checking purposes, with non-metals as well. 90 With some ingenuity he fixed up an arrangement, rather like that of an electric bell, whereby the limbs in contracting broke contact and in relaxing restored it, and so he managed to keep the frog in continuous rhythmical movement.

91 Whereas Galvani had been rightly convinced by his earlier observations that the movement in the specimens represented a reaction to an electric stimulus from outside, he now changed his mind. 92 In the very moment of his really significant discovery he succumbed to the error that he had to do with an effect of animal electricity located somewhere in the dead creature itself, 93 perhaps in the fashion of what had been observed in the electric fishes. 94 He decided that the metal attachment served merely to set in motion the electricity within the animal.

95 Whilst Galvani persisted in this mistake until his death, Volta realised that the source of the electric force, as in the first of Galvani's observations, must still be sought outside the specimens, and himself rightly attributed it to the contacting metals. 96 Guided by this hypothesis, Volta started systematic research into the Galvanic properties of metals, and

presently succeeded in producing electricity once more from purely mineral substances, namely from two different metals in contact with a conductive liquid.

97 This mode of producing electricity, however, differed from any previously known in allowing for the first time the production of continuous electrical effects. 98 It is this quality of the cells and piles constructed by Volta that laid open the road for electric force to assume that role in human civilisation which we have already described.

99 That Volta himself was aware of this essentially new factor in the Galvanic production of electricity is shown by his own report to the Royal Society: 100 'The chief of my results, and which comprehends nearly all the others, is the construction of an apparatus which resembles in its effects, viz. such as giving shocks to the arms, the Leyden phial, and still better electric batteries weakly charged; 101 . . . but which infinitely surpasses the virtue and power of these same batteries; as it has no need, like them, of being charged beforehand, by means of a foreign electricity; 102 and as it is capable of giving the usual commotion as often as ever it is properly touched.'

103 Whilst Volta's success was based on avoiding Galvani's error, his apparatus nevertheless turned out inadvertently to be a close counterpart of precisely that animal organ which Galvani had in mind when misinterpreting his own discoveries! 104 That Volta himself realised this is clear from the concluding words in his letter: 'This apparatus, as it resembles more the natural organ of the torpedo, or of the electrical eel, than the Leyden Phial or the ordinary electric batteries, I may call an artificial electric organ.' 105 This new method of producing continuous electrical effects had far-reaching results, one of which was the discovery of the magnetic properties of the electric current by the Dane, Oersted-- 106 once again a purely accidental discovery, moving directly counter to the assumptions of the discoverer himself. 107 About to leave the lecture room where he had just been trying to prove the non-existence of such magnetic

properties (an attempt seemingly crowned with success), Oersted happened to glance once more at his demonstration bench. 108 To his astonishment he noticed that one of his magnetic needles was out of alignment; evidently it was attracted by a magnetic field created by the current running through a wire he had just been using, which was still in circuit. 109 Thus what had escaped Oersted throughout his planned researches-- namely, that the magnetic force which accompanies an electric current must be sought in a direction at right angles to the current-- a fortuitous event enabled him to detect.

110 These repeated strokes of chance and frequently mistaken interpretations of the phenomenon thus detected show that people were exploring the electrical realm as it were in the dark; 111 it was a realm foreign to their ordinary ideas and they had not developed the forms of thought necessary for understanding it.-- And this, as our further survey will show, is still true, even to-day.

112 In our historical survey we come next to the researches of Faraday and Maxwell. 113 Faraday was convinced that if electrical processes are accompanied by magnetic forces, as Oersted had shown, the reverse must also be true-- magnetism must be accompanied by electricity. 114 He was led to this correct conviction by his belief in the qualitative unity of all the forces of Nature-- a reflexion, as his biography shows, of his strongly monotheistic, Old Testament faith. 115 Precisely this view, however-- which since Faraday natural science has quite consciously adopted as a leading principle-- will reveal itself to us as a fundamental error.

116 It seems paradoxical to assert that the more consistently human thought has followed this error, the greater have been the results of the scientific investigation of electricity. 117 Precisely this paradox, however, is characteristic of the realm of Nature to which electricity belongs; 118 and anyone earnestly seeking to overcome the illusions of our age will have to face the fact that the immediate effectiveness of an idea in practice is no proof of its ultimate truth.

MATTER

119 Another eloquent example of the strange destiny of human thought in connexion with electricity is to be found in the work of Clark Maxwell, who, starting from Faraday's discoveries, gave the theory of electricity its mathematical basis. 120 Along his purely theoretical line of thought he was led to the recognition of the existence of a form of electrical activity hitherto undreamt of-- electro-magnetic vibrations. 121 Stimulated by Maxwell's mathematical conclusions, Hertz and Marconi were soon afterwards able to demonstrate those phenomena which have led on the one hand to the electro-magnetic theory of light, and on the other to the practical achievements of wireless communication.

122 Once again, there is the paradoxical fact that this outcome of Maxwell's labours contradicts the very foundation on which he had built his theoretical edifice. 123 For his starting-point had been to form a picture of the electro-magnetic field of force to which he could apply certain well-known formulae of mechanics. 124 This he did by comparing the behaviour of the electrical force to the currents of an elastic fluid-- that is, of a material substance. 125 It is true that both he and his successors rightly emphasised that such a picture was not in any way meant as an explanation of electricity, but merely as an auxiliary concept in the form of a purely external analogy. 126 Nevertheless, it was in the guise of a material fluid that he thought of this force, and that he could submit it to mathematical calculation. 127 Yet the fact is that from this starting-point the strict logic of mathematics led him to the discovery that electricity is capable of behaviour which makes it appear qualitatively similar to ... light!

128 Whilst practical people were turning the work of Faraday and Maxwell to account by exploiting the mechanical working of electricity in power-production, and its similarity to light in the wireless communication of thought, 129 a new field of research, with entirely new practical possibilities, was suddenly opened up in the last

third of the nineteenth century through the discovery of how electricity behaves in rarefied air. 130 This brings us to the discovery of cathode rays and the phenomena accompanying them, from which the latest stage in the history of electricity originated. 131 And here once more, as in the history of Galvani's discoveries, we encounter certain undercurrents of longing and expectation in the human soul which seemed to find an answer through this sudden, great advance in the knowledge of electricity-- 132 an advance which has again led to practical applications of the utmost significance for human society, though not at all in the way first hoped for.

133 Interest in the phenomena arising when electricity passes through gases with reduced pressure had simultaneously taken hold of several investigators in the seventies of the nineteenth century. 134 But the decisive step in this sphere of research was taken by the English physicist, William Crookes. 135 He was led on by a line of thought which seems entirely irrelevant; 136 yet it was this which first directed his interest to the peculiar phenomena accompanying cathode rays; and they proved to be the starting-point of the long train of inquiry which has now culminated in the release of atomic energy.

137 In the midst of his many interests and activities, Crookes was filled from his youth with a longing to find by empirical means the bridge leading from the world of physical effects to that of superphysical causes. 138 He himself tells how this longing was awakened in him by the loss of a much-beloved brother. 139 Before the dead body he came to the question, which thereafter was never to leave him, whether there was a land where the human individuality continues after it has laid aside its bodily sheath, and how that land was to be found. 140 Seeing that scientific research was the instrument which modern human had forged to penetrate through the veil of external phenomena to the causes producing them, it was natural for Crookes to turn to it in seeking the way from the one world into the other.

MATTER

141 It was after meeting with a man able to produce effects within the corporeal world by means of forces quite different from those familiar to science, that Crookes decided to devote himself to this scientific quest. 142 Thus he first came into touch with that sphere of phenomena which is known as spiritualism, or perhaps more suitably, spiritism. 143 Crookes now found himself before a special order of happenings which seemed to testify to a world other than that open to our senses; 144 physical matter here showed itself capable of movement in defiance of gravity, manifestations of light and sound appeared without a physical source to produce them. 145 Through becoming familiar with such things at seances arranged by his mediumistic acquaintance, he began to hope that he had found the way by which scientific research could overstep the limits of the physical world. 146 Accordingly, he threw himself eagerly into the systematic investigation of his new experiences, and so became the father of modern scientific spiritism.

147 Crookes had hoped that the scientists of his day would be positively interested in his researches. 148 But his first paper in this field, 'On Phenomena called Spiritual', was at once and almost unanimously rejected by his colleagues, and as long as he concerned himself with such matters he suffered through their opposition. 149 It passed his understanding as a scientist why anything should be regarded in advance as outside the scope of scientific research. 150 After several years of fruitless struggle he broke off his investigations into spiritism, deeply disillusioned at his failure to interest official science in it. 151 His own partiality for it continued, however (he served as President of the Society for Psychical Research from 1896-9), and he missed no opportunity of confessing himself a pioneer in the search for the boundary-land between the worlds of matter and spirit. 152 Through all his varied scientific work the longing persisted to know more of this land.

153 Just as Crookes had once sought to investigate spiritism

scientifically, so in his subsequent scientific inquiries he was always something of a spiritist. 154 He admitted, indeed, that he felt specially attracted by the strange light effects arising when electricity passes through rarefied gases, because they reminded him of certain luminous phenomena he had observed during his spiritistic investigations. 155 Besides this, there was the fact that light here showed itself susceptible to the magnetic force in a way otherwise characteristic only of certain material substances. 156 Accordingly, everything combined to suggest to Crookes that here, if anywhere, he was at the boundary between the physical and the superphysical worlds. 157 No wonder that he threw himself into the study of these phenomena with enthusiasm.

158 He soon succeeded in evoking striking effects-- light and heat, and also mechanical-- along the path of electricity passing invisibly through the tube later named after him. 159 Thus he proved for the first time visibly, so to say, the double nature-- material and supermaterial-- of electricity. 160 What Crookes himself thought about these discoveries in the realm of the cathode rays we may judge from the title, 'Radiant Matter', or 'The Fourth State of Matter', which he gave to his first publication about them. 161 And so he was only being consistent when, in his lectures before the Royal Institution in London, and the British Association in Sheffield in 1879, after showing to an amazed scientific audience the newly discovered properties of electricity, 162 he came to the climax of his exposition by saying: 'We have seen that in some of its properties Radiant Matter is as material as this table, whilst in other properties it almost assumes the character of Radiant Energy. 163 We have actually touched here the borderland where Matter and Force seem to merge into one another, the shadowy realm between Known and Unknown, which for me has always had peculiar temptations.' 164 And in boldly prophetic words, which time has partly justified, he added, 'I venture to think that the greatest scientific problems of the future will find their solution in this

Borderland, and even beyond; here, it seems to me, lie Ultimate Realities, subtle, far-reaching, wonderful.'

165 No one can read these words of Crookes without hearing again, as an undertone, the question which had forced itself on him at the bedside of his dead brother, long before. 166 All that is left of the human being whom death has taken is a heap of substances, deserted by the force which had used them as the instrument of its own activity. 167 Whither vanishes this force when it leaves the body, and is there any possibility of its revealing itself even without occupying such a body?

168 Stirred by this question, the young Crookes set out to find a world of forces which differ from the usual mechanical ones exercised by matter on matter, 169 in that they are autonomous, superior to matter in its inert conglomeration, yet capable of using matter, just as the soul makes use of the body so long as it dwells within it. 170 His aim was to secure proof that such forces exist, or, at any rate, to penetrate into the realm where the transition from matter to pure, matter-free force takes place. 171 And once again, as in Galvani's day, electricity fascinated the eyes of a man who was seeking for the land of the soul. What spiritism denied, electricity seemed to grant.

172 The aversion to spiritism which Crookes met with in contemporary science was, from the standpoint of such a science, largely justified. 173 Science, in the form in which Crookes himself conceived it, took for granted that the relationship of human consciousness to the world was that of external onlooking. 174 Accordingly, if the scientist remained within the limits thus prescribed for consciousness, it was only consistent to refuse to make anything beyond these limits an object of scientific research.

175 On the other hand, it says much for the courage and open mindedness of Crookes that he refused to be held back from what was for him the only possible way of extending the boundaries of science beyond the given physical world. 176 Moreover, it was only natural that in his search for a world of a higher order than the

physical he should, as a man of his time, first turn his attention to spiritistic occurrences, 177 for spiritism, as it had come over to Europe from America in the middle of the nineteenth century, was nothing but an attempt by the onlooker-consciousness to learn something in its own way about the super-sensible world. 178 The spiritist expects the spirit to reveal itself in outwardly perceptible phenomena as if it were part of the physical world. 179 Towards the end of his life Crookes confessed that if he were able to begin again he would prefer to study telepathic phenomena-- 180 the direct transference of thought from one person to another-- rather than the purely mechanical, or so-called telekinetic, expressions of psychic forces. 181 But although his interest was thus turning towards a more interior field of psychic investigation, 182 he remained true to his times in still assuming that knowledge about the world, whatever it might be, could be won only by placing oneself as a mere onlooker outside the object of research.

183 The stream of new discoveries which followed Crookes's work justified his conviction that in cathode ray phenomena we have to do with a frontier region of physical Nature. 184 Still, the land that lies on the other side of this frontier is not the one Crookes had been looking for throughout his life. 185 For, instead of finding the way into the land whither human's soul disappears at death, Crookes had inadvertently crossed the border into another land-- a land which the twentieth-century scientist is impelled to call 'the country that is not ours'.

186 The realm thrown open to science by Crookes's observations, which human knowledge now entered as if taking it by storm, was that of the radioactive processes of the mineral stratum of the earth. 187 Many new and surprising properties of electricity were discovered there-- yet the riddle of electricity itself, instead of coming nearer, withdrew into ever deeper obscurity.

188 The very first step into this newly discovered territory made the riddle still more bewildering. 189 As we have said, Maxwell's

use of a material analogy as a means of formulating mathematically the properties of electro-magnetic fields of force had led to results which brought electricity into close conjunction with light. 190 In his own way Crookes focused, to begin with, his attention entirely on the light-like character of electric effects in a vacuum. 191 It was precisely these observations, however, as continued by Lenard and others, which presently made it necessary to see in electricity nothing else than a special manifestation of inert mass.

192 The developments leading up to this stage are recent and familiar enough to be briefly summarised. The first step was once more an accident, 193 when RÃ¶ntgen (or rather one of his assistants) noticed that a bunch of keys, laid down by chance on top of an unopened box of photographic plates near a cathode tube, had produced an inexplicable shadow-image of itself on one of the plates. 194 The cathode tube was apparently giving off some hitherto unknown type of radiation, capable of penetrating opaque substances. 195 RÃ¶ntgen was an experimentalist, not a theorist; his pupils used to say privately that in publishing this discovery of X-rays he attempted a theoretical explanation for the first and only time in his life-- and got it wrong!

196 However, this accidental discovery had far-reaching consequences. It drew attention to the fluorescence of minerals placed in the cathode tube; 197 this inspired Becquerel to inquire whether naturally fluorescent substances gave off anything like X-rays, and eventually-- yet again by accident-- he came upon certain uranium compounds. 198 These were found to give off a radiation similar to X-rays, and to give it off naturally and all the time. 199 Soon afterwards the Curies succeeded in isolating the element, radium, an element which was found to be undergoing a continuous natural disintegration. 200 The way was now clear for that long series of experiments on atomic disintegration which led finally to the splitting of the nucleus and the construction of the atomic bomb.

201 A typical modern paradox emerges from these results. By

restricting his cognitive powers to a field of experience in which the concept of force as an objective reality was unthinkable, 202 human has been led on a line of practical investigation the pursuit of which was bound to land him amongst the force-activities of the cosmos. 203 For what distinguishes electric and sub-electric activities from all other forces of physical Nature so far known to science, is that for their operation they have no need of the resistance offered by space-bound material bodies; 204 they represent a world of pure dynamics into which spatial limitations do not enter.

205 Equally paradoxical is the situation of theoretical thinking in face of that realm of natural being which practical research has lately entered. 206 We have seen that this thinking, by virtue of the consciousness on which it is founded, is impelled always to clothe its ideas in spatial form. 207 Wherever anything in the pure spatial adjacency of physical things remains inexplicable, resort is had to hypothetical pictures whose content consists once more of nothing but spatially extended and spatially adjacent items. 208 In this way matter came to be seen as consisting of molecules, molecules of atoms, and atoms of electrons, protons, neutrons, and so forth.

209 In so far as scientific thought has held to purely spatial conceptions, it has been obliged to concentrate on ever smaller and smaller spatial sizes, 210 so that the spatially conceived atom-picture has finally to reckon with dimensions wherein the old concept of space loses validity. 211 When once thinking had started in this direction, it was electricity which once more gave it the strongest impulse to go even further along the same lines.

212 Where we have arrived along this path is brought out in a passage in Eddington's ‘The Nature of the Physical World’. 213 There, after describing the modern picture of electrons dancing round the atomic nucleus, he says: 'This spectacle is so fascinating that we have perhaps forgotten that there was a time when we wanted to be told what an electron is. This question was never answered. 214 No familiar conceptions can be woven round the electron; it

belongs to the waiting list.' 215 The only thing we can say about the electron, if we are not to deceive ourselves, Eddington concludes, is: 'Something unknown is doing we don't know what.'

216 Let us add a further detail from this picture of the atom, as given in Eddington's Philosophy of Physical Science. 217 Referring to the so-called positron, the positive particle regarded as the polar opposite of the negative electron, he remarks: 'A positron is a hole from which an electron has been removed; 218 it is a bung-hole which would be evened up with its surroundings if an electron were inserted. ... You will see that the physicist allows himself even greater liberty than the sculptor. 219 The sculptor removes material to obtain the form he desires. The physicist goes further and adds material if necessary-- an operation which he describes as removing negative material. He fills up a bung-hole, saying he is removing a positron.' 220 Eddington thus shows to what paradoxical ideas the scientist is driven, when with his accustomed forms of thought he ventures into regions where the conditions necessary for such forms no longer exist; 221 and he concludes his remarks with the following caution: 'Once again I would remind you that objective truth is not the point at issue.'

222 By this reminder Eddington shows how far science has reconciled itself to the philosophic scepticism at which human's thinking had arrived in the days of Hume. 223 In so far as the above remark was intended to be a consolation for the bewildered student, it is poor comfort in the light of the actions which science has let loose with the help of those unknown entities. 224 For it is just this resignation of human thought which renders it unable to cope with the flood of phenomena springing from the sub-material realm of Nature, and has allowed scientific research to outrun scientific understanding.

GOETHEANISM -
WHENCE AND WHITHER?

THE ADVENTURE OF REASON
Ernst Lehrs

MATTER

5 In 1790, a year before Galvani's monograph, Concerning the Forces of Electricity, appeared, Goethe published his Metamorphosis of Plants, 2 which represents the first step towards the practical overcoming of the limitations of the onlooker-consciousness in science. 3 Goethe's paper was not destined to raise such a storm as soon followed Galvani's publication. And yet the fruit of Goethe's endeavours is not less significant than Galvani's discovery, for the progress of humankind. 4 For in Goethe's achievement lay the seed of that form of knowing which human requires, if in the age of the electrification of civilisation you are to remain master of your existence.

5 Among the essays in which Goethe in later years gave out some of the results of his scientific observation in axiomatic form, is one called 'Intuitive Judgment' ('Anschauende Urteilskraft'), 6 in which he maintains that he has achieved in practice what Kant had declared to be for ever beyond the scope of the human mind. 7 Goethe refers to a passage in the Critique of Judgment, where Kant defines the limits of human cognitional powers as he had observed them in his study of the peculiar nature of the human reason. 8 We must first go briefly into Kant's own exposition of the matter.

9 Kant distinguishes between two possible forms of reason, the intellectus archetypus and the intellectus ectypus. 10 By the first he means a reason 'which being, not like ours, discursive, but intuitive, proceeds from the synthetic universal (the intuition of the whole as such) to the particular, that is, from the whole to the parts'. 11 According to Kant, such a reason lies outside human possibilities. 12 In contrast to it, the intellectus ectypus peculiar to human is restricted to taking in through the senses the single details of the world as such; 13 with these it can certainly construct pictures of their totalities, but these pictures never have more than a hypothetical character and can claim no reality for themselves. 14 Above all, it is not given to such a thinking to think 'wholes' in such a way that

through an act of thought alone the single items contained in them can be conceived as parts springing from them by necessity. 15 To illustrate this, we may say that, according to Kant, we can certainly comprehend the parts of an organism, say of a plant, and out of its components make a picture of the plant as a whole; 16 but we are not in a position to think that 'whole' of the plant which conditions the existence of its organism and brings forth its parts by necessity.

17 Kant expresses this in the following way: 'For external objects as phenomena an adequate ground related to purposes cannot be met with; 18 this, although it lies in Nature, must be sought only in the super-sensible substrata of Nature, from all possible insight into which we are cut off. 19 Our understanding has then this peculiarity as concerns the judgment, that in cognitive understanding the particular is not determined by the universal and cannot therefore be derived from it.'

20 The attempt to prove whether or not another form of reason than this (the intellectus archetypus) is possible-- even though declared to be beyond human-- Kant regarded as superfluous, 21 because the fact was enough for him 'that we are led to the Idea of it-- which contains no contradiction-- 22 in contrast to our discursive understanding, which has need of images (intellectus ectypus), and to the contingency of its constitution'.

23 Kant here brings forward two reasons why it is permissible to conceive of the existence of an extra-human, archetypal reason. 24 On the one hand he admits that the existence of our own reason in its present condition is of a contingent order, and thus does not exclude the possible existence of a reason differently constituted. 25 On the other hand, he allows that we can think of a form of reason which in every respect is the opposite of our own, without meeting any logical inconsistency.

26 From these definitions emerges a conception of the properties of human's cognitional powers which agrees exactly with those on which, as we have seen, Hume built up his whole philosophy. 27

Both allow to the reason a knowledge-material consisting only of pictures-- 28 that is, of pictures evoked in consciousness through sense-perception, and received by it from the outer world in the form of disconnected units, whilst denying it all powers, as Hume expressed it, ever 'to perceive any real connections between distinct existences'.

29 This agreement between Kant and Hume must at first sight surprise us, when we recall that, as already mentioned, Kant worked out his philosophy precisely to protect the cognising being of human from the consequences of Hume's thought. 30 For, as he himself said, it was his becoming acquainted with Hume's Treatise that 'roused him out of his dogmatic slumber' and obliged him to reflect on the foundations of human knowing. 31 We shall understand this apparent paradox, however, if we take it as a symptom of humanity's close imprisonment in recent centuries within the limits of its onlooker-consciousness.

32 In his struggle against Hume, Kant was not concerned to challenge his opponent's definition of human's reasoning power. 33 His sole object was to show that, if one accepted this definition, one must not go as far as Hume in the application of this power. 34 All that Kant could aspire to do was to protect the ethical from attack by the intellectual part of human, and to do this by proving that the former belongs to a world into which the latter has no access. 35 For with the will human belongs to a world of purposeful doing, whereas the reason, as our quotations have shown, is incapable even in observing external Nature, of comprehending the wholes within Nature which determine natural ends. 36 Still less can it do this in regard to human, a being who in his actions is integrated into higher purposes.

37 Kant's deed is significant in that it correctly drew attention to that polar division in human nature which, after all, was already established in Kant's own time. 38 Kant demonstrated also that to win insight into the ethical nature of human with the aid of the isolated intellect alone implied a trespass beyond permissible limits. 39 In

order to give the doing part of the human being its necessary anchorage, however, Kant assigned it to a moral world-order entirely external to human, to which it could be properly related only through obedient submission.

40 In this way Kant became the philosopher of that division between knowledge and faith which to this day is upheld in both the ecclesiastical and scientific spheres of our civilisation.

41 Nevertheless, he did not succeed in safeguarding humanity from the consequences of Hume's philosophy; 42 for human cannot live indefinitely in the belief that with the two parts of own being you are bound up with two mutually unrelated worlds. 43 The time when this was feasible is already over, as may be seen from the fact that ever greater masses of people wish to determine their behaviour according to their own ideas, 44 and as they see no alternative in the civilisation around them but to form ideas by means of the discursive reason which inevitably leads to agnosticism, they determine their actions accordingly. 45 Meanwhile, the ethical life as viewed by Kant accordingly shrinks ever further into a powerless, hole-and-corner existence.

46 It is Goethe's merit to have first shown that there is a way out of this impasse. He had no need to argue theoretically with Kant as to the justification of denying human any power of understanding apart from the discursive, 47 and of leaving the faculty of intuitive knowledge to a divinity somewhere outside the world of human. 48 For Goethe was his own witness that Kant was mistaken in regarding human's present condition as his lasting nature. 49 Let us hear how he expresses himself on this fact at the beginning of his essay written as an answer to Kant's statement:

50 'It is true, the author here seems to be pointing to an intellect not human but divine. 51 And yet, if in the moral sphere we are supposed to lift ourselves up to a higher region through faith in God, Virtue and Immortality, so drawing nearer to the Primal Being, why should it not be likewise in the intellectual? 52 By contemplation

(Anschauen) of an ever-creative nature, may we not make ourselves worthy to be spiritual sharers in her productions? 53 I at first, led by an inner urge that would not rest, had quite unconsciously been seeking for the realm of Type and Archetype, and my attempt had been rewarded: 54 I had been able to build up a description, in conformity with Nature Herself. 55 Now therefore nothing more could hinder me from braving what the Old Human of the King's Hill2 himself calls the Adventure of Reason.'

56 Goethe started from the conviction that our senses as well as our intellect are gifts of Nature, 57 and that, if at any given moment they prove incapable through their collaboration of solving a riddle of Nature, we must ask Her to help us to develop this collaboration adequately. 58 Thus there was no question for him of any restriction of sense-perception in order to bring the latter in line with the existing power of the intellect, 59 but rather to learn to make an ever fuller use of the senses and to bring our intellect into line with what they tell. 60 'The senses do not deceive, but the judgment deceives', is one of his basic utterances concerning their respective roles in our quest for knowledge and understanding. 61 As to the senses themselves, he was sure that 'the human being is adequately equipped for all true earthly requirements if he trusts his senses, and so develops them as to make them worthy of trust'.

62 There is no contradiction in the statement that we have to trust our senses, and that we have to develop them to make them trustworthy. 63 For, 'Nature speaks upwards to the known senses of human, downwards to unknown senses of human'. 64 Goethe's path was aimed at wakening faculties, both perceptual and conceptual, which lay dormant in himself. 65 His experience showed him that 'every process in Nature, rightly observed, wakens in us a new organ of cognition'. 66 Right observation, in this respect, consisted in a form of contemplating Nature which he called a 're-creating (creating in the wake) of an ever-creative Nature' (Nachschaffen einer immer schaffenden Natur).

MATTER

67 We should do Goethe an injustice if we measured the value of his scientific work by the amount of factual knowledge he contributed to one or other sphere of research. 68 Although Goethe did bring many new things to light, as has been duly recognised in the scientific fields concerned, it cannot be gainsaid that other scientists in his own day, working along the usual lines, far exceeded his total of discoveries. 69 Nor can it be denied that, as critics have pointed out, he occasionally went astray in reporting his observations. 70 These things, however, do not determine the value or otherwise of his scientific labours. 71 His work draws its significance not so much from the 'what', to use a Goethean expression, as from the 'how' of his observations, that is, from his way of investigating Nature. 72 Having once developed this method in the field of plant observation, Goethe was able, with its aid, to establish a new view of animal nature, to lay the basis for a new meteorology, 73 and, by creating his theory of light and colour, to provide a model for a research in the field of physics, free from onlooker-restrictions.

74 In the scientific work of Goethe his botanical studies have a special place. 75 As a living organism, the plant is involved in an endless process of becoming. It shares this characteristic, of course, with the higher creatures of Nature, and yet between it and them there is an essential difference. 76 Whereas in animal and human a considerable part of the life-processes conceal themselves within the organism, 77 in order to provide a basis for inner soul processes, the plant brings its inner life into direct and total outer manifestation. 78 Hence the plant, better than anything, could become Goethe's first teacher in his exercise of re-creating Nature.

79 It is for the same reason that we shall here use the plant for introducing Goethe's method. 80 The following exposition, however, does not aim at rendering in detail Goethe's own botanical researches, expounded by him in two extensive essays, Morphology and The Metamorphosis of Plants, as well as in a series of smaller writings.

MATTER

81 There are several excellent translations of the chief paper, the Metamorphosis, from which the English-speaking reader can derive sufficient insight into Goethe's way of expressing his ideas; a pleasure as well as a profit which he should not deny himself.

82 Our own way of procedure will have to be such that Goethe's method, and its fruitfulness for the general advance of science, come as clearly as possible into view. Botanical details will be referred to only as far as seems necessary for this purpose.

83 The data for observation, from which in Goethe's own fashion we shall start, have been selected as best for our purpose, quite independently of the data used by Goethe himself. 84 Our choice was determined by the material available when these pages were being written. The reader is free to supplement our studies by his own observation of other plants.

85 Plates II and III show two series of leaves which are so arranged as to represent definite stages in the growth-process of the plant concerned. 86 In each sequence shown the leaves have been taken from a single plant, in which each leaf-form was repeated, perhaps several times, before it passed over into the next stage. 87 The leaves on Plate II come from a Sidalcea (of the mallow family), those on Plate III from a Delphinium. 88 We will describe the forms in sequence, so that we may grasp as clearly as possible the transition from one to another as presented to the eye.

89 Starting with the right-hand leaf at the bottom of Plate II, we let our eye and mind be impressed by its characteristic form, seeking to take hold of the pattern after which it is shaped. 90 Its edge bears numerous incisions of varying depths which, however, do not disturb the roundness of the leaf as a whole. 91 If we re-create in our imagination the 'becoming' of such a leaf, that is, its gradual growth in all directions, we receive an impression of these incisions as 'negative' forms, 92 because, at the points where they occur, the multiplication of the cells resulting from the general growth has been retarded. We observe that this holding back follows a certain order. 93 We now proceed to the

next leaf on the same plate and observe that, whilst the initial plan is faithfully maintained, the ratio between the positive and negative forms has changed. 94 A number of incisions, hardly yet indicated in the first leaf, have become quite conspicuous. The leaf begins to look as if it were breaking up into a number of subdivisions.

95 In the next leaf we find this process still further advanced. The large incisions have almost reached the centre, while a number of smaller ones at the periphery have also grown deeper into the leaf. 96 The basic plan of the total leaf is still maintained, but the negative forms have so far got the upper hand that the original roundness is no longer obvious.

97 The last leaf shows the process in its extreme degree. As we glance back and along the whole series of development, we recognise that the form of the last leaf is already indicated in that of the first. 98 It appears as if the form has gradually come to the fore through certain forces which have increasingly prevented the leaf from filling in the whole of its ground-plan with matter. 99 In the last leaf the common plan is still visible in the distribution of the veins, but the fleshy part of the leaf has become restricted to narrow strips along these veins.

100 The metamorphosis of the delphinium leaf (Plate III) is of a different character. Here the plant begins with a highly elaborate form of the leaf, while in the end nothing remains but the barest indication of it. 101 The impression received from this series of leaves is that of a gradual withdrawal of the magnificent form, revealed in its fullness only in the first leaf.

102 A more intense impression of what these metamorphoses actually mean is achieved by altering our mode of contemplation in the following way. 103 After repeated and careful observation of the different forms on either of the plates, we build up inwardly, as a memory picture, the shape of the first leaf, 104 and then transform this mental image successively into the images of the ensuing forms until we reach the final stage. 105 The same process can also be tried retrogressively, and so repeated forward and backward.

106 This is how Goethe studied the doing of the plant, and it is by this method that he discovered the spiritual principle of all plant life, and succeeded also in throwing a first light on the inner life-principle of animals.

107 We chose the transformation of leaf forms into one another as the starting-point of our observations, because the principle of metamorphosis appears here in a most conspicuous manner. 108 This principle, however, is not confined to this part of the plant's organism. 109 In fact, all the different organs which the plant produces within its life cycle-- foliage, calyx, corolla, organs of fertilisation, fruit and seed-- are metamorphoses of one and the same organ.

110 Human has long learn't to make use of this law of metamorphosis in the plant for what is called doubling the flower of a certain species. 111 Such a flower crowds many additional petals within its original circle, and these petals are nothing but metamorphosed stamens; this, for instance, is the difference between the wild and the cultivated rose. 112 The multitude of petals in the latter is obtained by the transformation of a number of the former's innumerable stamens. (Note the intermediate stages between the two, often found inside the flower of such plants.)

113 This falling back from the stage of an organ of fertilisation to that of a petal shows that the plant is capable of regressive metamorphosis, 114 and we may conclude from this that in the normal sequence the different organs are transformed from one another by way of progressive metamorphosis. 115 It is evident that the regressive type occurs only as an abnormality, or as a result of artificial cultivation. 116 Plants once brought into this condition frequently show a general state of unrest, so that other organs also are inclined to fall back to a lower level. 117 Thus we may come across a rose, an outer petal of which appears in the form of a leaf of the calyx (sepal), or one of the sepals is found to have grown into an ordinary rose leaf.

118 We now extend our mental exercise to the plant's whole

organism. By a similar mental effort as applied to the leaf-formations we strive to build up a complete plant. 119 We start with the seed, from which we first imagine the cotyledons unfolding, letting this be followed by the gradual development of the entire green part of the plant, its stem and leaves, until the final leaves change into the sepals of the calyx. 120 These again we turn into the petals of the flower, until via pistil and stamens the fruit and seed are formed.

121 By pursuing in this way the living doing of the plant from stage to stage we become aware of a significant rhythm in its total life cycle. 122 This, when first discovered by Goethe, gave him the key to an understanding of Nature's general procedure in building living organisms, and in maintaining life in them.

123 The plant clearly divides into three major parts: firstly, the one that extends from the cotyledons to the calyx, the green part of the plant, that is, where the life principle is most active; 124 secondly, the one comprising the flower itself with the organs of fertilisation, where the vitality of the plant gives way to other principles; and lastly, the fruit and seed, which are destined to be discharged from the mother organism. 125 Each of these three contains two kinds of organs: first, organs with the tendency to grow into width-leaf, flower and fruit; 126 second, organs which are outwardly smaller and simpler, but have the function of preparing the decisive leaps in the plant's development: these are the calyx, the stamens, etc., and the seed.

127 In this succession, Goethe recognised a certain rhythm of expansion and contraction, and he found that the plant passes through it three times during any one cycle of its life. 128 In the foliage the plant expands, in the calyx it contracts; it expands again in the flower and contracts in the pistil and stamens; finally, it expands in the fruit and contracts in the seed.

129 The deeper meaning of this threefold rhythm will become clear when we consider it against the background of what we observed in the metamorphosis of the leaf. 130 Take the mallow leaf; its metamorphosis shows a step-

wise progression from coarser to finer forms, whereby the characteristic plan of the leaf comes more and more into view, so that in the topmost leaf it reaches a certain stage of perfection. 131 Now we observe that in the calyx this stage is not improved on, but that the plant recurs to a much simpler formation.

132 Whilst in the case of the mallow the withdrawal from the stage of the leaf into that of the calyx occurs with a sudden leap, we observe that the delphinium performs this process by degrees. 133 Whilst the mallow reaches the highly elaborate form of the leaf only in the final stage, the delphinium leaps forth at the outset, 134 as it were, with the fully accomplished leaf, and then protracts its withdrawal into the calyx over a number of steps, so that this process can be watched with our very eyes. 135 In this type of metamorphosis the last leaf beneath the calyx shows a form that differs little from that of a calyx itself, with its simple sepals. Only in its general geometrical arrangement does it still remind us of the original pattern.

136 In a case like this, the stem-leaves, to use Goethe's expression, 'softly steal into the calyx stage'. 137 In the topmost leaf the plant has already achieved something which, along the other line of metamorphosis, is tackled only after the leaf plan itself has been gradually executed. 138 In this case the calyx stage, we may say, is attained at one leap.

139 Whatever type of metamorphosis is followed by a plant-- and there are others as well, so that we may even speak of metamorphoses between different types of metamorphosis!-- 140 they all obey the same basic rule, namely, that before proceeding to the next higher stage of the cycle, the plant sacrifices something already achieved in a preceding one. 141 Behind the inconspicuous sheath of the calyx we see the plant preparing itself for a new creation of an entirely different order. 142 As successor to the leaf, the flower appears to us time and again as a miracle.

143 Nothing in the lower realm of the plant predicts the form, colour,

scent and all the other properties of the new organ produced at this stage. 144 The completed leaf, preceding the plant's withdrawal into the calyx, represents a triumph of structure over matter. 145 Now, in the flower, matter is overcome to a still higher degree. It is as if the material substance here becomes transparent, so that what is immaterial in the plant may shine through its outer surface.

146 In this 'climbing up the spiritual ladder' Goethe learned to recognise one of Nature's basic principles. 147 He termed it Steigerung (heightening). Thus he saw the plant develop through Metamorphosis and Heightening towards its consummation. 148 Implicit in the second of these two principles, however, there is yet another natural principle for which Goethe did not coin a specific term, 149 although he shows through other utterances that he was well aware of it, and of its universal significance for all life. We propose to call it here the principle of Renunciation.

150 In the life of the plant this principle shows itself most conspicuously where the green leaf is heightened into the flower. 151 While progressing from leaf to flower the plant undergoes a decisive ebb in its vitality. Compared with the leaf, the flower is a dying organ. 152 This dying, however, is of a kind we may aptly call a 'dying into being'. 153 Life in its mere vegetative form is here seen withdrawing in order that a higher manifestation of the spirit may take place. 154 The same principle can be seen at work in the insect kingdom, when the caterpillar's tremendous vitality passes over into the short-lived beauty of the butterfly. 155 In the human being it is responsible for that metamorphosis of organic processes which occurs on the path from the metabolic to the nervous system, and which we came to recognise as the precondition for the appearance of consciousness within the organism.

156 What powerful forces must be at work in the plant organism at this point of transition from its green to its coloured parts! 157 They enforce a complete halt upon the juices that rise up right into the calyx, so that these bring nothing

of their life-bearing activity into the formation of the flower, but undergo a complete transmutation, not gradually, but with a sudden leap.

158 After achieving its masterpiece in the flower, the plant once more goes through a process of withdrawal, this time into the tiny organs of fertilisation. 159 We shall return later to this essential stage in the life cycle of the plant, and shall then clear up the misinterpretation put upon it ever since scientific biology began. 160 After fertilisation, the fruit begins to swell; once more the plant produces an organ with a more or less conspicuous spatial extension. 161 This is followed by a final and extreme contraction in the forming of the seed inside the fruit. 162 In the seed the plant gives up all outer appearance to such a degree that nothing seems to remain but a small, insignificant speck of organised matter. 163 Yet this tiny, inconspicuous thing bears in it the power of bringing forth a whole new plant.

164 In these three successive rhythms of expansion and contraction the plant reveals to us the basic rule of its existence. 165 During each expansion, the active principle of the plant presses forth into visible appearance; 166 during each contraction it withdraws from outer embodiment into what we may describe as a more or less pure state of being. 167 We thus find the spiritual principle of the plant engaged in a kind of breathing rhythm, now appearing, now disappearing, now assuming power over matter, now withdrawing from it again.

168 In the fully developed plant this rhythm repeats itself three times in succession and at ever higher levels, so that the plant, in climbing from stage to stage, each time goes through a process of withdrawal before appearing at the next. 169 The greater the creative power required at a certain stage, the more nearly complete must be the withdrawal from outer appearance. 170 This is why the most extreme withdrawal of the plant into the state of being takes place in the seed, when the plant prepares itself for its transition from one generation to another. 171 Even earlier, the flower stands towards the leaves as something

like a new generation springing from the small organ of the calyx, as does the fruit to the flower when it arises from the tiny organs of reproduction. 172 In the end, however, nothing appears outwardly so unlike the actual plant as the little seed which, at the expense of all appearance, has the power to renew the whole cycle.

173 Through studying the plant in this way Goethe grew aware also of the significance of the nodes and eyes which the plant develops as points where its vital energy is specially concentrated; 174 not only the seed, but the eye also, is capable of producing a new, complete plant. 175 In each of these eyes, formed in the axils of the leaves, the power of the plant is present in its entirety, very much as in each single seed.

176 In other ways, too, the plant shows its capacity to act as a whole at various places of its organism. Otherwise, no plant could be propagated by cuttings; 177 in any little twig cut from a parent plant, all the manifold forces operative in the gathering, transmuting, forming of matter, that are necessary for the production of root, leaf, flower, fruit, etc, are potentially present, ready to leap into action provided we give it suitable outer conditions. 178 Other plants, such as gloxinia and begonia, are known to have the power of bringing forth a new, complete plant from each of their leaves. 179 From a small cut applied to a vein in a leaf, which is then embedded in earth, a root will soon be seen springing downward, and a stalk with leaves rising upward.

180 A particular observation made by Goethe in this respect is of interest for methodological reasons. 181 In the introduction to his treatise Metamorphosis of Plants, when referring to the regressive metamorphosis of stamens into petals as an example of an irregular metamorphosis, 182 he remarks that 'experiences of this kind of metamorphosis will enable us to disclose what is hidden from us in the regular way of development, and to see clearly and visibly what we should otherwise only be able to infer'. 183 In this remark Goethe expresses a truth that is valid in many spheres of life, both human

and natural. 184 It is frequently a pathological aberration in an organic entity that allows us to see in physical appearance things that do not come outwardly to the fore in the more balanced condition of normal development, although they are equally part of the regular organic process.

185 An enlightening experience of this kind came to Goethe's aid when one day he happened to see a 'proliferated' rose (durchgewachsene Rose), that is, a rose from whose centre a whole new plant had sprung. 186 Instead of the contracted seed-pod, with the attached, equally contracted, organs of fertilisation, there appeared a continuation of the stalk, half red and half green, bearing in succession a number of small reddish petals with traces of anthers. 187 Thorns could be seen appearing further up, petals half-turned into leaves, and even a number of fresh nodes from which little imperfect flowers were budding. 188 The whole phenomenon, in all its irregularity, was one more proof for Goethe that the plant in its totality is potentially present at each point of its organism.

189 Goethe's observation of the single plant in statu agendi had trained him to recognise things of quite different outer appearance as identical in their inner nature. 190 Leaf, sepal, petal, etc., much as they differ outwardly, yet showed themselves to him as manifestations of one and the same spiritual archetype. 191 His idea of Metamorphosis enabled him to reduce what in outer appearance seems incompatibly different to its common formative principle. 192 His next step was to observe the different appearances of one and the same species in different regions of the earth, 193 and thus to watch the capacity of the species to respond in a completely flexible way to the various climatic conditions, yet without concealing its inner identity in the varying outer forms. 194 His travels in Switzerland and Italy gave him opportunity for such observations, and in the Alpine regions especially he was delighted at the variations in the species which he already knew so well from his home in Weimar. 195

He saw their proportions, the distances between the single parts, the degree of lignification, the intensity of colour, etc., varying with the varied conditions, yet never concealing the identity of the species.

196 Having once advanced in his investigations from metamorphosis in the parts of the single plant to metamorphosis among different representatives of single plant species, 197 Goethe had to take only one further, entirely decisive, step in order to recognise how every member of the plant kingdom is the manifestation of a single formative principle common to them all. 198 He was thus faced with the momentous task of preparing his spirit to think an idea from which the plant world in its entire variety could be derived.

199 Goethe did not take such a step easily, for it was one of his scientific principles never to think out an idea prematurely. 200 He was well aware that he who aspires to recognise and to express in idea the spirit which reveals itself through the phenomena of the sense-world must develop the art of waiting-- of waiting, however, in a way intensely active, 201 whereby one looks again and yet again, until what one looks at begins to speak and the day at last dawns when, through tireless 're-creation of an ever-creating Nature', one has grown ripe to express her secrets openly. Goethe was a master in this art of active waiting.

202 It was in the very year that Galvani, through his chance discovery, opened the way to the overwhelming invasion of humankind by the purely physical forces of Nature, that Goethe came clearly to see that he had achieved the goal of his labours. 203 We can form some picture of the decisive act in the drama of his seeking and finding from letters written during the years 1785-7.

204 In the spring of 1785 he writes to a friend in a way that shows him fully aware of his new method of studying Nature, which he recognised was a reading of Her phenomena: 205 'I can't tell you how the Book of Nature is becoming readable to me. My long practice in spelling has helped me; it now suddenly works, and my

quiet joy is inexpressible.' 206 Again in the summer of the following year: 'It is a growing aware of the Form with which again and again Nature plays, and, in playing, brings forth manifold life.'

207 Then Goethe went on his famous journey to Italy which was to bear such significant fruit for his inner life, both in art and in science. 208 At Michaelmas, 1786, he reports from his visit to the botanical garden in Padua that 'the thought becomes more and more living that it may be possible out of one form to develop all plant forms'. 209 At this moment Goethe felt so near to the basic conception of the plant for which he was seeking, that he already christened it with a special name. 210 The term he coined for it is Urpflanze, literally rendered archetypal plant, or ur-plant, as we propose quite simply to call it.

211 It was the rich tropical and sub-tropical vegetation in the botanical gardens in Palermo that helped Goethe to his decisive observations. 212 The peculiar nature of the warmer regions of the earth enables the spirit to reveal itself more intensively than is possible in the temperate zone. 213 Thus in tropical vegetation many things come before the eye which otherwise remain undisclosed, and then can be detected only through an effort of active thought. 214 From this point of view, tropical vegetation is 'abnormal' in the same sense as was the proliferated rose which confirmed for Goethe's physical perception that inner law of plant-growth which had already become clear to his mind.

215 During his sojourn in Palermo in the spring of 1787 Goethe writes in his notebook: 'There must be one (ur-plant): how otherwise could we recognise this or that formation to be a plant unless they were all formed after one pattern?' 216 Soon after this, he writes in a letter to the poet Herder, one of his friends in Weimar: 'Further, I must confide to you that I am quite close to the secret of plant creation, and that it is the simplest thing imaginable. 217 The ur-plant will be the strangest creature in the world, for which Nature Herself should envy me. 218 With this model and the key to it one will be

able to invent plants ad infinitum; they would be consistent; 219 that is to say, though non-existing, they would be capable of existing, being no shades or semblances of the painter or poet, but possessing truth and necessity. The same law will be capable of extension to all living things.'

220 To become more familiar with the conception of the ur-plant, let us bring the life-cycle of the plant before our inner eye once again. 221 There, all the different organs of the plant-leaf, blossom, fruit, etc, appear as the metamorphic revelations of the one, identical active principle, 222 a principle which gradually manifests itself to us by way of successive heightening from the cotyledons to the perfected glory of the flower. 223 Amongst all the forms which thus appear in turn, that of the leaf has a special place; for the leaf is that organ of the plant in which the ground-plan of all plant existence comes most immediately to expression. 224 Not only do all the different leaf forms arise, through endless changing, out of each other, but the leaf, in accordance with the same principle, also changes itself into all the other organs which the plant produces in the course of its growth.

225 It is by precisely the same principle that the ur-plant reveals itself in the plant kingdom as a whole. 226 Just as in the single plant organism the different parts are a graduated revelation of the ur-plant, so are the single kinds and species within the total plant world. 227 As we let our glance range over all its ranks and stages-- from the single-celled, almost formless alga to the rose and beyond to the tree--, we are following, step by step, the revelation of the ur-plant. 228 Barely hinting at itself in the lowest vegetable species, it comes in the next higher stages into ever clearer view, finally streaming forth in full glory in the magnificence of the manifold blossoming plants. 229 Then, as its highest creation, it brings forth the tree, which, itself a veritable miniature earth, becomes the basis for innumerable single plant growths.

230 It has struck biologists of Goethe's own and later times that contrary to their method he did not

build up his study of the plant by starting with its lowest form, and so the reproach has been levelled against him of having unduly neglected the latter. 231 Because of this, the views he had come to were regarded as scientifically unfounded. Goethe's note-books prove that there is no justification for such a reproach. 232 He was in actual fact deeply interested in the lower plants, but he realised that they could not contribute anything fundamental to the spiritual image of the plant as such which he was seeking to attain. 233 To understand the plant he found himself obliged to pay special attention to examples in which it came to its most perfect expression. For what was hidden in the alga was made manifest in the rose. 234 To demand of Goethe that in accordance with ordinary science he should have explained Nature 'from below upwards' is to misunderstand the methodological basis of all his investigations.

235 Seen with Goethe's eyes, the plant kingdom as a whole appears to be a single mighty plant. 236 In it the ur-plant, while pressing into appearance, is seen to observe the very rule which we have found governing its action in the single plant-- that of repeated expansion and contraction. 237 Taking the tree in the sense already indicated, as the state of highest expansion along the ur-plant's way of entering into spatial manifestation, we note that tree-formation occurs successively at four different levels-- 238 as fern-tree (also the extinct tree-form of the horsetail) among the cryptogams, as coniferous tree among the gymnosperms, as palm-tree among the monocotyledons, 239 and lastly in the form of the manifold species of the leaf-trees at the highest level of the plant kingdom, the dicotyledons. 240 All these levels have come successively into existence, as geological research has shown; 241 the ur-plant achieved these various tree-formations successively, thus giving up again its state of expansion each time after having reached it at a particular level.

242 From the concept of the ur-plant Goethe soon learned to develop another concept which was to express the spiritual principle working in a particular

plant species, 243 just as the ur-plant was the spiritual principle covering the plant kingdom as a whole. 244 He called it the type. In the manifold types which are thus seen active in the plant world we meet offsprings, as it were, of the mother, the 'ur-plant', which in them assumes differentiated modes of action.

245 The present part of our discussion may be concluded by the introduction of a concept which Goethe formed for the organ of cognition attained through contemplating Nature in the state of becoming, as the plant had taught him to do.

246 Let us look back once again on the way in which we first tried to build up the picture of leaf metamorphosis. 247 There we made use, first of all, of exact sense-perceptions to which we applied the power of memory in its function as their keeper. 248 We then endeavoured to transform within our mind the single memory pictures (leaf forms) into one another. By doing so we applied to them the activity of mobile fantasy. 249 In this way we actually endowed, on the one hand, objective memory, which by nature is static, with the dynamic properties of fantasy, and, on the other hand, mobile fantasy, which by nature is subjective, with the objective character of memory. 250 Now, for the new organ of cognition arising from the union of these two polar faculties of the soul, Goethe coined the significant expression, exact sensorial fantasy. 251 In terms of our knowledge of human's psycho-physical make-up, acquired earlier, we can say that, just as the nervous system forms the basis for memory, and the blood the basis for fantasy, so the 'exact sensorial fantasy' is based on a newly created collaboration of the two.

252 Our observations have reached a point where we may consider that stage in the life cycle of the single plant where, by means of the process of pollination, the seed acquires the capacity to produce out of itself a new example of the species. 253 Our discussion of this will bring home the fundamental difference in idea that arises when, instead of judging a process from the standpoint of the mere

onlooker, we try to comprehend it through re-creating it inwardly.

254 Biological science of our day takes it for granted that the process uniting pollen with seed in the plant is an act of fertilisation analogous to that which occurs among the higher organisms of Nature. 255 Now it is not to be gainsaid that to external observation this comparison seems obvious, and that it is therefore only natural to speak of the pollen as the male, and of the ovule as the female, element, 256 and of their union as entirely parallel to that between the sexes in the higher kingdoms of Nature. 257 Goethe confesses that at first he himself 'had credulously put up with the ruling dogma of sexuality'. 258 He was first made aware of the invalidity of this analogy by Professor Schelver who, as Superintendent of the Jena Botanical Institute, was working under Goethe's direction and had trained himself in Goethe's method of observing plants. 259 This man had come to see that if one held strictly to the Goethean practice of using nothing for the explanation of the plant but what one could read from the plant itself, one must not ascribe to it any sexual process. 260 He was convinced that for a Goethean kind of biology it must be possible to find, even for the process of pollination, an idea derived from nothing but the two principles of plant life: growth and formation. 261 Goethe immediately recognised the Tightness of this thought, and set about the task of relating the pollination process to the picture of the plant which his investigations had already yielded. 262 His way of reporting the result shows how fully conscious he was of its revolutionary nature. Nor was he in any doubt as to the kind of reception it would be given by official biology.

263 In observing the growth of the plant, Goethe had perceived that this proceeds simultaneously according to two different principles. 264 On the one hand the plant grows in an axial direction and thereby produces its main and side stems. To this growth principle Goethe gave the name 'vertical tendency'. 265 Were the plant to follow this principle only, its lateral shoots would all stand vertically one above the other. 266

But observation shows that the different plant species obey very different laws in this respect, as may be seen if one links up all the leaf buds along any plant stem; they form a line which winds spiral fashion around it. 267 Each plant family is distinguishable by its own characteristic spiral, which can be represented either geometrically by a diagram, or arithmetically by a fraction. 268 If, for example, the leaves are so arranged in a plant that every fifth leaf recurs on the same side of the stem, while the spiral connecting the five successive leaf-buds winds twice round the stem, this is expressed in botany by the fraction 2/5. 269 To distinguish this principle of plant growth from the vertical tendency, Goethe used the term 'spiral tendency'.

270 To help towards a clear understanding of both tendencies, Goethe describes an exercise which is characteristic of his way of schooling himself in what he called exact sensorial fantasy. 271 He first looks out for a phenomenon in which the 'secret' of the spiral tendency is made 'open'. This he finds in such a plant as the convolvulus; 272 in this kind of plant the vertical tendency is lacking, and the spiral principle comes obviously into outer view. 273 Accordingly, the convolvulus requires an external support, around which it can wind itself. 274 Goethe now suggests that after looking at a convolvulus as it grows upwards around its support, one should first make this clearly present to one's inner eye, 275 and then again picture the plant's growth without the vertical support, allowing instead the upward-growing plant inwardly to produce a vertical support for itself. 276 By way of inward re-creation (which the reader should not fail to carry out yourself) Goethe attained a clear experience of how, in all those plants which in growing upwards produce their leaves spiral-wise around the stem, the vertical and spiral tendencies work together.

277 In following the two growth-principles, Goethe saw that the vertical comes to a halt in the blossom; 278 the straight line here shrinks together, so to say, into a point, surviving only in the ovary and pistil as continuations of the

plant's stalk. 279 The spiral tendency, on the other hand, is to be found in the circle of the stamens arranged around these; 280 the process which in the leaves strove outwards in spiral succession around a straight line is now telescoped on to a single plane. 281 In other words, the vertical-spiral growth of the plant here separates into its two components. 282 And when a pollen grain lands on a pistil and joins with the ovule prepared in the ovary, the two components are united again. Out of the now complete seed a new and complete plant can arise.

283 Goethe understood that he would be taught a correct conception of this process only by the plant itself. 284 Accordingly, he asked himself where else in the growing plant something like separation and reunion could be seen. 285 This he found in the branching and reuniting of the veins in the leaves, known as anastomosis.

286 In the dividing of the two growth-principles in the plant through the formation of carpel and pistil, on the one hand, and the pollen-bearing stamens on the other, 287 and in their reunion through the coming together of the pollen with the seed, Goethe recognised a metamorphosis of the process of anastomosis at a higher level. His vision of it caused him to term it 'spiritual anastomosis'.

288 Goethe held a lofty and comprehensive view of the significance of the male and female principles as spiritual opposites in the cosmos. 289 Among the various manifestations of this polarity in earthly nature he found one, but one only, in the duality of the sexes as characteristic of human and animal. 290 Nothing compelled him, therefore, to ascribe it in the same form to the plant. This enabled him to discover how the plant bore the same polarity in plant fashion.

291 In the neighbourhood of Weimar, Goethe often watched a vine slinging its foliaged stem about the trunk and branches of an elm tree. 292 In this impressive sight Nature offered him a picture of 'the female and male, the one that needs and the one that gives, side by side in the vertical and

spiral directions'. 293 Thus his artist's eye clearly detected in the upward striving of the plant a decisively masculine principle, and in its spiral winding an equally definite feminine principle. 294 Since in the normal plant both principles are inwardly connected, 'we can represent vegetation as a whole as being in a secret androgynous union from the root up. 295 From this union, through the changes of growth, both systems break away into open polarity and so stand in decisive opposition to each other, only to unite again in a higher sense.'

296 Thus Goethe found himself led to ideas regarding the male and female principles in the plant, which were the exact opposite of those one obtains 297 if, in trying to explain the process of pollination, one does not keep to the plant itself but imports an analogy from another kingdom of Nature. 298 For in continuance of the vertical principle of the plant, the pistil and carpel represent the male aspect in the process of spiritual anastomosis, and the mobile, wind-- or insect-borne pollen, in continuing the spiral principle, represents the female part.

299 If the process of pollination is what the plant tells us it is, then the question arises as to the reason for the occurrence of such a process in the life cycle of the fully developed plant. 300 Goethe himself has not expressed himself explicitly on this subject. But his term 'spiritual anastomosis' shows that he had some definite idea about it. 301 Let us picture in our mind what happens physically in the plant as a result of pollination and then try to read from this picture, as from a hieroglyph, what act of the spiritual principle in the plant comes to expression through it.

302 Without pollination there is no ripening of the seed. 303 Ripening means for the seed its acquisition of the power to bring forth a new and independent plant organism through which the species continues its existence within Nature. 304 In the life cycle of the plant this event takes place after the organism has reached its highest degree of physical perfection. 305 When we now read these facts in the light of the

knowledge that they are deeds of the activity of the type, we may describe them as follows:

306 Stage by stage the type expends itself in ever more elaborate forms of appearance, until in the blossom a triumph of form over matter is reached. 307 A mere continuation of this path could lead to nothing but a loss of all connexion between the plant's superphysical and physical component parts. 308 Thus, to guarantee for the species its continuation in a new generation, the formative power of the type must find a way of linking itself anew to some part of the plant's materiality. 309 This is achieved by the plant's abandoning the union between its two polar growth-principles and re-establishing it again, 310 which in the majority of cases takes place even in such a way that the bearers of the two principles originate from two different organisms.

311 By picturing the process in this way we are brought face to face with a rule of Nature which, once we have recognised it, proves to hold sway at all levels of organic nature. 312 In general terms it may be expressed as follows: In order that spiritual continuity may be maintained within the coming and going multitude of Nature's creations, the physical stream must suffer discontinuity at certain intervals. 313 In the case of the plant this discontinuity is achieved by the breaking asunder of the male and female growth-principles. 314 When they have reunited, the type begins to abandon either the entire old plant or at least part of it, according to whether the species is an annual or a perennial one, in order to concentrate on the tiny seed, setting, as it were, its living seal on it.

315 This is as far as we can go in describing this mysterious process, at least at the present stage of our considerations.

316 Our pursuit of Goethe's way of observing the life of the plant has brought us to a point where it becomes possible to rectify a widespread error concerning his position as an evolutionary theorist. 317 Goethe has been honourably mentioned as a predecessor of Darwin. 318 The truth is, that the idea of evolution

emerging from Goethe's mode of regarding Nature is the exact opposite of the one held by Darwin and-- in whatever modified form-- by his followers. 319 A brief consideration of the Darwinian concepts of inheritance and adaptation will show this.

320 Goethe's approach to his conception of the type is clear evidence that he did not undervalue the factor of adaptation as a formative element in Nature; 321 we have seen that he became acquainted with it in studying the same plant species under different climatic conditions. 322 In his view, however, adaptation appears not as the passive effect of a blindly working, external cause, but as the response of the spiritual type to the conditions meeting it from outside.

323 The same applies to the concept of inheritance. Through inheritance Goethe saw single, accessory characteristics of a species being carried over from one generation to the next; 324 but never could the reappearance of the basic features of the species itself be explained in this way.

325 He was sufficiently initiated into Nature's methods to know that She was not in need of a continuity of the stream of physical substance, 326 in the sense of the theory of inheritance, to guarantee a continuance of the features of the species through successive generations, 327 but that it was Her craft to achieve such continuance by means of physical discontinuity.

328 Goethe was not temperamentally given to reflecting deliberately about his own cognitional processes. 329 Moreover, the excess of reflexion going on around him in the intellectual life of his younger days inclined him to guard himself with a certain anxiety against philosophical cogitations. 330 His words to a friend - 'Dear friend, I have done it well, and never reflected about thinking'-- bring this home to us. 331 If in his later years Goethe could become to some degree epistemologically conscious of his spiritual achievements, 332 as, for instance, his essay on Intuitive Judgment shows, he owed this to his friendship with Schiller, who

became for him a kind of soul mirror, in which he could see the reflexion of his own processes of consciousness. 333 Indeed, at their first personal encounter, significant as it was for their whole later relationship, Schiller--though all unconsciously--performed a decisive service of this kind for him. 334 Goethe himself speaks of the occasion in his essay Happy Encounter (Gliickliches Ereignis), written twelve years after Schiller's death. 335 The occasion was, outwardly regarded, fortuitous: both men were leaving a lecture on natural science at the University of Jena, Schiller having been present as Professor of History in the University, and Goethe as its patron and as a Weimar Minister of State. 336 They met at the door of the lecture hall and went out into the street together. 337 Schiller, who had been wanting to come into closer contact with Goethe for a long time, used the opportunity to begin a conversation. 338 He opened with a comment on the lecture they had just heard, saying that such a piecemeal way of handling Nature could not bring the layman any real satisfaction. 339 Goethe, to whom this remark was heartily welcome, replied that such a style of scientific observation 'was uncanny even for the initiated, 340 and that there must certainly be another way altogether, which did not treat of Nature as divided and in pieces, but presented Her as working and alive, striving out of the whole into the parts'.

341 Schiller's interest was at once aroused by this remark, although as a thorough Kantian he could not conceal his doubts whether the kind of thing indicated by Goethe was within human capacity. 342 Goethe began to explain himself further, and so the discussion proceeded, until the speakers arrived at Schiller's house. 343 Quite absorbed in his description of plant metamorphosis, Goethe went in with Schiller and climbed the stairs to the latter's study. 344 Once there, he seized pen and paper from Schiller's writing desk, and to bring his conception of the ur-plant vividly before his companion's eyes he made 'a symbolic plant appear with many a characteristic stroke of the pen'.

MATTER

345 Although Schiller had listened up to this point 'with great interest and definite understanding', he shook his head as Goethe finished, and said-- Kantian that he was at that time: 'That is no experience, that is an idea.' 346 These words were very disappointing to Goethe. At once his old antipathy towards Schiller rose up, an antipathy caused by much in Schiller's public utterances which he had found distasteful.

347 Once again he felt that Schiller and he were 'spiritual antipodes, removed from each other by more than an earth diameter'. 348 However, Goethe restrained his rising annoyance, and answered Schiller in a tranquil but determined manner: 'I am glad to have ideas without knowing it, and to see them with my very eyes.'

349 Although at this meeting Goethe and Schiller came to no real agreement, the personal relationship formed through it did not break off; both had become aware of the value of each to the other. 350 For Goethe his first meeting with Schiller had the significant result of showing him that 'thinking about thought' could be fruitful. 351 For Schiller this significance consisted in his having met in Goethe a human intellect which, simply by its existing properties, invalidated Kant's philosophy. 352 For him Goethe's mind became an object of empirical study on which he based the beginnings of a new philosophy free from onlooker-restrictions.

353 An essay, written by Goethe about the same time as the one just quoted, shows how he came to think at a later date about the raising of human perception into the realm of ideas. 354 In this essay, entitled Discovery of an Excellent Predecessor, Goethe comments on certain views of the botanist, K. F. Wolff, regarding the relationships between the different plant organs, which seemed to be similar to his own, and at which Wolff had arrived in his own way.

355 Wolff had risen up as an opponent of the so-called preformation theory, still widespread at that time, according to which the entire plant with all its different parts is already present in embryonic physical form in the

seed, and simply grows out into space through physical enlargement. 356 Such a mode of thought seemed inadmissible to Wolff, for it made use of an hypothesis 'resting on an extra-sensible conception, 357 which was held to be thinkable, although it could never be demonstrated from the sense world. 358 Wolff laid it down as a fundamental principle of all research that 'nothing may be assumed, admitted or asserted that has not been actually seen and cannot be made similarly visible to others'. 359 Thus in Wolff we meet with a phenomenologist who in his way tried to oppose certain trends of contemporary biological thinking. 360 As such, Wolff had made certain observations which caused him to ascribe to the plant features quite similar to those which Goethe had grasped under the conception of progressive and regressive metamorphosis. 361 In this way Wolff had grown convinced that all plant organs are transformed leaves. 362 True to his own principle, he had then turned to the microscope for his eyes to confirm what his mind had already recognised. 363 The microscope gave him the confirmation he expected by showing that all the different organs of the plant develop out of identical embryonic beginnings. 364 In his absolute reliance on physical observation, however, he tried to go further than this and to detect in this way the reason why the plant does not always bring forth the same organ. 365 He saw that the vegetative strength in the plant diminishes in proportion as its organism enters upon its later stages. 366 He therefore attributed the differentiated evolution of plant organs from identical beginnings to an ever weaker process of development in them.

367 Despite his joy in Wolff as someone who in his own fashion had arrived at certain truths which he himself had also discovered, 368 and despite his agreement with Wolff's phenomenalistic principle, Goethe could in no way accept his explanation of why metamorphosis took place in plants. 369 He said: 'In plant metamorphosis Wolff saw how the same organ continuously draws together, makes itself smaller; he did not see that this contraction alternates with an

expansion. 370 He saw that the organ diminishes in volume, but not that at the same time it ennobles itself, and so, against reason, he attributed decline to the path towards perfection.' 371 What was it, then, which had prevented Wolff from seeing things aright? 372 'However admirable may be Wolff's method, through which he has achieved so much, the excellent person never thought that there may be a difference between seeing and seeing, 373 that the eyes of the spirit have to work in perpetual living connection with those of the body, for one otherwise risks seeing and yet seeing past a thing (zu sehen und doch vorbeizusehen).'

374 Wolff's case was to Goethe a symptom of the danger which he saw arising for science from the rapidly increasing use of the microscope-- and similarly the telescope--, if thinking was not developed correspondingly but left at the mercy of these instruments. 375 His concern over the state of affairs speaks from his utterance: 'Microscopes and telescopes, in actual fact, confuse human's innate clarity of mind.'

376 When we follow Goethe in this way he comes before us in characteristic contrast to Robert Hooke. 377 We remember Hooke's microscopic 'proof of the unrelatedness of human thought to outer reality (Chapter III). 377 There can be no doubt how Goethe, if the occasion had arisen, would have commented on Hooke's procedure. 378 He would have pointed out that there would be no such thing as a knife with its line-like edge unless human were able to think the concept 'line', nor a needle with its point-like end unless he were able to think the concept 'point'. 379 In fact, knife and needle are products of a human action which is guided by these two concepts respectively. 380 As such they are embodiments, though more or less imperfect ones, of these concepts. Here too, therefore, just as Goethe had discovered it through his way of observing the plant, we see Ideas with our very eyes. 381 What distinguishes objects of this kind from organic entities, such as the plant, is the different relationship between Object and Idea. 382 Whereas in the case of an

organism the Idea actively indwells the object, its relationship to a human-made thing-- and similarly to Nature's mineral entities-- is a purely external one. 383 Hooke, so Goethe would have argued, allowed the microscope to confuse his common sense. 384 He would have seen in him an example confirming his verdict that you who fails to let the eye of the spirit work in union with the eye of the body 'risks seeing yet seeing past the thing'.

385 'Thus not through an extraordinary spiritual gift, not through momentary inspiration, unexpected and unique, but through consistent work did I eventually achieve such satisfactory results.' 386 These words of Goethe - they occur in his essay, History of my Botanical Studies, which he wrote in later life as an account of his labours in this field of science-- 387 show how anxious he was that it should be rightly understood that the faculty of reading in the Book of Nature, as he knew it, was the result of a systematic training of his mind. 388 It is important for our further studies to make clear to ourselves at this point the nature of the change which human must bring to pass within the self in order to brave Kant's 'adventure of reason'. 389 Goethe's concept for the newly acquired faculty of cognition, exact sensorial fantasy, can give us the lead.

390 We remember that, to form this faculty, two existing functions of the soul, as such polarically opposite, had to be welded together-- memory based on exact sense-perception and the freely working fantasy; 391 one connected with the nervous system of the body, the other with the blood. 392 We also know from earlier considerations (Chapter II) that in the little child there is not yet any such polarisation, in body or soul, as there is in human's later life. 393 Thus we see that training on Goethe's lines aims at nothing less than restoring within oneself a condition which is natural in early childhood.

EXCEPT WE BECOME …
Ernst Lehrs

6 In this chapter we shall concern ourselves with a number of

personalities from the more or less recent past of the cultural life of Britain, each of whom was a spiritual kinsman of Goethe, 2 and so a living illustration of the fact that the true source of knowledge in human must be sought, and can be found, outside the limits of own modern adult consciousness. 3 Whilst none of them was a match for Goethe as regards universality and scientific lucidity, they are all characteristic of an immediacy of approach to certain essential truths, which in the sense we mean is not found in Goethe. 4 It enabled them to express one or the other of these truths in a form that makes them suitable as sign-posts on our own path of exploration. 5 We shall find repeated opportunity in the later pages of this book to remember just what these men saw and thought.

6 The first is Thomas Reid (1710-96), the Scottish philosopher and advocate of common sense as the root of philosophy. 7 After having served for some years as a minister in the Church of Scotland, Reid became professor of Philosophy at the University of Aberdeen, whence he was called to Glasgow as the successor of Adam Smith. 8 Through his birth in Strachan, Kincardine, he belonged to the same part of Scotland from which Kant's ancestors had come. 9 Two brief remarks of Goethe show that he knew of the Scotsman's philosophy, and that he appreciated his influence on contemporary philosophers.

10 Reid, like his contemporary Kant, felt his philosophical conscience stirred by Hume's Treatise of Human Nature, and, like Kant, set himself the task of opposing it. 11 Unlike Kant, however, whose philosophic system was designed to arrest human's reason before the abyss into which Hume threatened to cast it, Reid contrives to detect the bridge that leads safely across this abyss. 12 Even though it was not granted to him actually to set foot on this bridge (this, in his time, only Goethe managed to do), he was able to describe it in a manner especially helpful for our own purpose.

13 The first of the three books in which Reid set out the results of his labours appeared in 1764 under the title, ‘*Inquiry into the Human*

Mind on the Principles of Common Sense'. 14 The other two, Essays on the '*Intellectual Powers of Human*' and Essays on the '*Active Powers of Human*', appeared twenty years later. 15 In these books Reid had in view a more all-embracing purpose than in his first work. 16 The achievement of this purpose, however, required a greater spiritual power than was granted to him. 17 Comparing his later with his earlier work, Reid's biographer, A. Campbell Fraser, says: 'Reid's Essays form, as it were, the inner court of the temple of which the Aberdonian Inquiry is the vestibule. 18 But the vestibule is a more finished work of constructive skill than the inner court, for the aged architect appears at last as if embarrassed by accumulated material. 19 The Essays, greater in bulk, perhaps less deserve a place among modern philosophical classics than the Inquiry, 20 notwithstanding its narrower scope, confined as it is to human's perception of the extended world, as an object lesson on the method of appeal to common sense.'

21 Whilst the ideas of Kant, by which he tried in his way to oppose Hume's philosophy, have become within a short space of time the common possession of people's minds, it was the fate of Reid's ideas to find favour among only a restricted circle of friends. 22 Moreover, they suffered decisive misunderstanding and distortion through the efforts of well-meaning disciples. 23 This was because Kant's work was a late fruit of an epoch of human development which had lasted for centuries and in his time began to draw to its close, while Reid's work represents a seed of a new epoch yet to come. 24 Here lies the reason also for his failure to develop his philosophy beyond the achievements contained in his first work. 25 It is on the latter, therefore, that we shall chiefly draw for presenting Reid's thoughts.

26 The convincing nature of Hume's argumentation, together with the absurdity of the conclusions to which it led, aroused in Reid a suspicion that the premises on which Hume's thoughts were built, 27 and which

he, in company with all his predecessors, had assumed quite uncritically, contained some fundamental error. 28 For both as a Christian, a philosopher, and a man in possession of common sense, Reid had no doubt as to the absurdity and destructiveness of the conclusions to which Hume's reasoning had led him.

29 For my own satisfaction, I entered into a serious examination of the principles upon which this sceptical system is built; 30 and was not a little surprised to find that it leans with its whole weight upon a hypothesis, which is ancient indeed, and hath been very generally received by philosophers, but of which I could find no solid proof. 31 The hypothesis I mean is, That nothing is perceived but what is in the mind which perceives it: 32 That we do not really perceive the things that are external, but only certain images and pictures of them imprinted upon the mind, which are called impressions and ideas.

33 'If this be true, supposing certain impressions and ideas to exist presently in my mind, I cannot, from their existence, infer the existence of anything else; 34 my impressions and ideas are the only existences of which I can have any knowledge or conception; and they are such fleeting and transitory beings, that they can have no existence at all, any longer than I am conscious of them. 35 So that, upon this hypothesis, the whole universe about me, bodies and spirits, sun, moon, stars, and earth, friends and relations, all things without exception, which I imagined to have a permanent existence whether I thought of them or not vanish at once: 36 'And, like the baseless fabric of this vision ... Leave not a rack behind.

37 'I thought it unreasonable, upon the authority of philosophers, to admit a hypothesis which, in my opinion, overturns all philosophy, all religion and virtue, and all common sense: 38 and finding, that all the systems which I was acquainted with, were built upon this hypothesis, I resolved to enquire into this subject anew, without regard to any hypothesis.' 39 The following passage from the first chapter of the Inquiry reveals

Reid as a personality who was not dazzled to the same extent as were his contemporaries by the brilliance of the onlooker-consciousness: 40 'If it [the mind] is indeed what the Treatise of Human Nature makes it, I find I have been only in an enchanted castle, imposed upon by spectres and apparitions. 41 I blush inwardly to think how 1 have been deluded; I am ashamed of my frame, and can hardly forbear expostulating with my destiny: 42 Is this thy pastime, O Nature, to put such tricks upon a silly creature, and then to take off the mask, and show him how he hath been befooled? 43 If this is the philosophy of human nature, my soul enter thou not into her secrets. 44 It is surely the forbidden tree of knowledge; I no sooner taste it, than I perceive myself naked, and stript of all things-- yea even of my very self. 45 I see myself, and the whole frame of Nature, shrink into fleeting ideas, which, like Epicurus's atoms, dance about in emptiness.

46 'But what if these profound disquisitions into the first principles of human nature, do naturally and necessarily plunge a person into this abyss of scepticism? 47 May we not reasonably judge from what hath happened? 48 DesCartes no sooner began to dig in this mine, than scepticism was ready to break in upon him. He did what he could to shut it out. 49 Malebranche and Locke, who dug deeper, found the difficulty of keeping out this enemy still to increase; but they laboured honestly in the design. 50 Then Berkeley, who carried on the work, despairing of securing all, bethought himself of an expedient: 51 By giving up the material world, which he thought might be spared without loss, and even with advantage, he hoped by an impregnable partition to secure the world of spirits. 52 But, alas! the Treatise of Human Nature wantonly sapped the foundation of this partition and drowned all in one universal deluge.'

53 What Reid so pertinently describes here as the 'enchanted castle' is nothing else than the human head, which knows of no occurrence beyond its boundaries, 54 because it has forgotten that it is only the end-product of a living

existence outside of, and beyond, itself. 55 We see here that Reid is gifted with the faculty of entering this castle without forfeiting his memory of the world outside; and so even from within its walls, he could recognise its true nature. 56 To a high degree this helped him to keep free of those deceptions to which the majority of his contemporaries fell victim, and to which so many persons are still subject to-day.

57 It is in this way that Reid could make it one of the cardinal principles of his observations to test all that the head thinks by relating it to the rest of human nature and to allow nothing to stand, which does not survive this test. 58 In this respect the argument he sets over against the Cartesian, 'cogito ergo sum' is characteristic: ' "I am thinking," says he, "therefore I am": 59 and is it not as good reasoning to say, I am sleeping, therefore I am? If a body moves, it must exist, no doubt; but if it is at rest, it must exist likewise.'

60 The following summarises the position to which Reid is led when he includes the whole human being in his philosophical inquiries.

61 Reid admits that, when the consciousness that has become aware of itself surveys that which lies within its own horizon, it finds nothing else there but transient pictures. 62 These pictures in themselves bring to the mind no experience of a lasting existence outside itself. 63 There is no firm evidence of the existence of either an outer material world to which these pictures can be related, or of an inner spiritual entity which is responsible for them. 64 To be able to speak of an existence in either realm is impossible for a philosophy which confines its attention solely to the mere picture-content of the waking consciousness.

65 But human is not only a percipient being; you are also a being of will, and as such you comes into a relationship with the world which can be a source of rich experience. 66 If one observes this relationship, one is bound to notice that it is based on the self-evident assumption that one possesses a lasting individuality, whose actions deal with a lasting

material world. 67 Any other way of behaviour would contradict the common sense of human; where we meet with it we are faced with a lunatic.

68 Thus philosophy and common sense seem to stand in irreconcilable opposition to each other. But this opposition is only apparent. 69 It exists so long as philosophy thinks it is able to come to valid conclusions without listening to the voice of common sense, believing itself to be too exalted to need to do so. 70 Philosophy, then, does not realise 'that it has no other root but the principles of Common Sense; it grows out of them, and draws its nourishment from them: severed from this root, its honours wither, its sap is dried up, it dies and rots.' 71 At the moment when the philosophical consciousness ceases to regard itself as the sole foundation of its existence 72 and recognises that it can say nothing about itself without considering the source from which it has evolved, it attains the possibility of seeing the content of its experience in a new light. 73 For it is no longer satisfied with considering this content in the completed form in which it presents itself. 74 Rather does it feel impelled to investigate the process which gives rise to this content as an end-product (the 'impressions' and 'ideas' of Hume and his predecessors).

75 Reid has faith in the fact-- for his common sense assures him of it-- that a lasting substantiality lies behind the world of the senses, even if for human consciousness it exists only so long as impressions of it are received via the bodily senses. 76 Similarly, he has faith in the fact that his consciousness, although existing but intermittently, has as its bearer a lasting self. 77 Instead of allowing this intuitively given knowledge to be shaken by a mere staring at fugitive pictures, behind which the real existence of self and world is hidden, 78 he seeks instead in both directions for the origin of the pictures and will not rest until he has found the lasting causes of their transient appearances.

79 In one direction Reid finds himself led to the outer boundary of the body, where sense perception has its origin. 80 This

prompts him to investigate the perceptions of the five known senses: smelling, tasting, hearing, touching and seeing, which he discusses in this order. 81 In the other direction he finds himself led-- and here we meet with a special attribute of Reid's whole philosophical outlook-- to the realm of human speech. 82 For speech depends upon an inner, intelligent human activity, which, once learn't, becomes a lasting part of human's being, quite outside the realm of his philosophising consciousness, and yet forming an indispensable instrument for this consciousness.

83 The simplest human reasoning, prompted only by common sense, and the subtlest philosophical thought, both need language for their expression. 84 Through your ability to speak, human lifts the self above an instinctive animal existence, and yet develops this ability at an infantile stage, 85 when, in so far as concerns the level of own consciousness and own relationship to the world, you hardly rises above the level of the animal. 86 It requires a highly developed intelligence to probe the intricacies of language, yet complicated tongues were spoken in human history long before human awoke to own individual intelligence. 87 Just as each person learns to think through speaking, so did humanity as a whole. 88 Thus speech can become a means for acquiring insight into the original form of human intelligence. 89 For in speech the common sense of human, working unconsciously within you, meets the fully awakened philosophical consciousness.

90 The way in which the two paths of observation have here been set out must not give rise to the expectation that they are discussed by Reid in a similarly systematic form. 91 For this, Reid lacked the sufficient detachment from his own thoughts. 92 As he presents his observations in the Inquiry they seem to be nothing but a systematic description of the five senses, broken into continually by linguistic considerations of the kind indicated above. 93 So, for example, many of his more important statements about language are found in his chapter on 'Hearing'.

MATTER

94 Our task will be to summarise Reid's work, taking from his description, so often full of profound observations, only what is essential to illustrate his decisive discoveries. 95 This requires that (keeping to Mr. Eraser's picture) we consider separately the two pillars supporting the roof of the temple's forecourt: speech and sense-impressions. We will start with speech.

96 Reid notes as a fundamental characteristic of human language that it includes two distinct elements: 97 first, the purely acoustic element, represented by the sheer succession of sounds, and secondly the variety of meanings represented by various groups of sounds, meanings which seem to have nothing to do with the sounds as such. 98 This state of language, where the sound-value of the word and its value as a sign to denote a thing signified by it, have little or nothing to do with one another, is certainly not the primeval one. 99 In the contemporary state of language, which Reid calls artificial language, we must see a development from a former condition, which Reid calls natural language. 100 So long as this latter condition obtained, human expressed in the sound itself what you felt impelled to communicate to your fellows. 101 In those days sound was not merely an abstract sign, but a gesture, which moreover was accompanied and supported by the gestures of the limbs.

102 Even to-day human, at the beginning of your life, still finds yourself in that relationship to language which was natural to all humans in former times. 103 The little child acquires the ability to speak through the imitation of sounds, becoming aware of them long before it understands the meaning accorded to the various groups of sounds in the artificial state of contemporary adult speech. 104 That the child's attention should be directed solely to the sound, and not to the abstract meaning of the individual words, is indeed the prerequisite of learning to speak. 105 If, says Reid, the child were to understand immediately the conceptual content of the words it hears, it would never learn to speak at all.

106 When the adult of to-day uses language in its artificial state, words are only signs for things signified by them. 107 As you speaks, your attention is directed exclusively towards this side of language; the pure sound of the words you uses remains outside the scope of your awareness. 108 The little child, on the other hand, has no understanding of the meaning of words and therefore lives completely in the experience of pure sound. 109 In the light of this, Reid comes to the conclusion, so important for what follows, that with the emergence of a certain form of consciousness, in this case that of the intellectual content of words, 110 another form submerges, a form in which the experience of the pure sound of words prevails. 111 The adult, while in one respect ahead of the child, yet in another is inferior, for the effect of this change is a definite impoverishment in soul-experience. 112 Reid puts this as follows: 'It is by natural signs chiefly that we give force and energy to language; and the less language has of them, it is the less expressive and persuasive. 113 Artificial signs signify, but they do not express; they speak to the understanding, as algebraic characters may do, but the passions and the affections and the will hear them not: 114 these continue dormant and inactive, till we speak to them in the language of Nature, to which they are all attention and obedience.'

115 We have followed Reid so far in his study of language, because it is along this way that he came to form the concepts that were to serve him as a key for his all-important findings in the realm of sense-experience. 116 These are the concepts which bear on the connexion between the sign and the thing signified; the distinction between the artificial and the natural state of language; and the disappearance of certain primeval human capacities for experience, 117 of which Reid says that they are brought by the child into the world, but fade as his intellectual capacities develop.

118 As soon as one begins to study Reid's observations in the realm of sense-experience, one meets with a certain difficulty, noticeable earlier but not so strikingly. 119

The source of it is that Reid was obliged to relate the results of his observations only to the five senses known in his day, whereas in fact his observations embrace a far greater field of human sense-perception. 120 Thus a certain disharmony creeps into his descriptions and makes his statements less convincing, especially for someone who does not penetrate to its real cause.

121 However this may be, it need not concern us here; what matter to us are Reid's actual observations. 122 For these led him to the important distinction between two factors in our act of acquiring knowledge of the outer world, each of which holds an entirely different place in ordinary consciousness. 123 Reid distinguishes them as 'sensation' and 'perception'. It is through the latter that we become aware of the object as such. 124 But we are mistaken if we regard the content of this perception as identical with the sum total of the sensations which are caused in our consciousness by the particular object. 125 For these sensations are qualitatively something quite different, and, although without them no perception of the object is possible, they do not by themselves convey a knowledge of the thing perceived. 126 Only, because our attention is so predominantly engaged by the object under perception, we pay no heed to the content of our sensation.

127 To take an example, the impressions of roundness, angularity, smoothness, roughness, colour, etc., of a table contain, all told, nothing that could assure us of the existence of the object 'table' as the real content of an external world. 128 How, then, do we receive the conviction of the latter's existence? Reid's answer is, by entering into an immediate intuitive relationship with it. 129 It is true that to establish this relationship we need the stimuli coming from the impressions which our mind receives through the various senses. Yet this must not induce us to confuse the two.

130 When Nature speaks to human through your senses, something occurs exactly analogous to the process when human communicates with human

through the spoken word. 131 In both cases the perception, that is, the result of the process of perception, is something quite other than the sum of sensations underlying it. 132 Per-ceiving by means of the senses is none other than a re-ceiving of Nature's language; and this language, just like human language, bears two entirely different elements within it. 133 According as one or the other element prevails in human's intercourse with Nature, this intercourse will be either 'natural' or 'artificial'-- to use the terms by which Reid distinguished the two stages of human speech.

134 Just as every human being must once have listened only to the pure sound of the spoken word on a wholly sentient level in order to acquire the faculty of speaking, 135 so also, in order to learn Nature's language, the soul must once have been totally surrendered to the pure impressions of the senses. 136 And just as with time the spoken word becomes a symbol for that which is signified by it, the consciousness turning to the latter and neglecting the actual sound-content of the word, 137 so also in its intercourse with Nature the soul, with its growing interest in the thing signified, turns its attention more and more away from the actual experiences of the senses.

138 From this it follows that a philosophy which seeks to do justice to human's whole being must not be satisfied with examining the given content of human consciousness, but must strive to observe the actual process to which this content owes its emergence. 139 In practice this means that a philosopher who understands own task aright must strive to reawaken in the self a mode of experience which is naturally given to human in own early childhood. 140 Reid expresses this in the Inquiry in the following way: 'When one is learning a language, one attends to the sounds, but when one is master of it, one attends only to the sense of what one would express. 141 If this is the case, we must become as little children again, if we will be philosophers: we must overcome habits which have been gathering strength ever since we began to think; 142 habits, the

usefulness of which atones for the difficulty it creates for the philosopher in discovering the first principles of the human mind.'

143 'We must become as little children again, if we will be philosophers!' 144 The phrase appears here almost in passing, and Reid never came back to it again. And yet in it is contained the Open Sesame which gives access to the hidden spirit-treasures of the world. 145 In this unawareness of Reid's of the importance of what he thus had found we must see the reason for his incapacity to develop his philosophy beyond its first beginnings. 146 This handicap arose from the fact that in all his thinking he was guided by a picture of the being of human which-- as a child of his time, dominated by the contemporary religious outlook-- he could never realise distinctly. 147 Yet without a clear conception of this picture no justice can be done to Reid's concept of common sense. 148 Our next task, therefore, must be to evoke this picture as clearly as we can

149 The following passage in Reid's Inquiry provides a key for the understanding of his difficulty in conceiving an adequate picture of human's being. 150 In this passage Reid maintains that all art is based on human's experience of the natural language of things, 151 and that in every human being there lives an inborn artist who is more or less crippled by human's growing accustomed to the state of artificial language in your intercourse with the world.

152 In continuation of the passage quoted earlier Reid says: 'It were easy to show, that the fine arts of the musician, the painter, the actor, and the orator, so far as they are expressive; 153 although the knowledge of them requires in us a delicate taste, a nice judgment, and much study and practice; 154 yet they are nothing else but the language of Nature, which we brought into the world with us, but have unlearned by disuse and so find the greatest difficulty in recovering it.

155 'Abolish the use of articulate sounds and writing among humankind for a century, and every human would be a painter,

an actor, and an orator. 156 We mean not to affirm that such an expedient is practicable; or if it were, that the advantage would counterbalance the loss; 157 but that, as humans are led by Nature and necessity to converse together they will use every means in their power to make themselves understood; 158 and where they cannot do this by artificial signs, they will do it as far as possible by natural ones: and you that understands perfectly the use of natural signs, must be the best judge in all expressive arts.'

159 When Reid says that there are certain characteristics-- and these just of the kind whose development truly ennobles human life-- which the soul brings with it into the world, 160 a picture of human is evoked in us in which the super-sensible part of your being appears as an entity whose existence reaches further back than the moment of birth and even the first beginnings of the body. 161 Now such a conception of human is in no way foreign to humanity, in more ancient times it was universally prevalent, and it still lives on to-day, if merely traditionally, in the eastern part of the world. 162 It is only in the West that from a certain period it ceased to be held. This was the result of a change which entered into human memory in historical times, 163 just as the re-dawning of the old knowledge of human's pre-existence, of which Reid is a symptom, is a result of another corresponding alteration in the memory-powers of human in modern times.

164 For people of old it was characteristic that alongside the impressions they received in earthly life through the senses (which in any case were far less intense than they are to-day), 165 they remembered experiences of a purely super-sensible kind, which gave them assurance that before the soul was knit together with a physical body it had existed in a cosmic state purely spiritual in nature. 166 The moment in history when this kind of memory disappeared is that of the transition from the philosophy of Plato to that of Aristotle. 167 Whereas Plato was convinced by clear knowledge that the soul possesses characteristics implanted in it

before conception, 168 Aristotle recognised a bodiless state of the soul only in the life after death. For him the beginning of the soul's existence was identical with that of the body.

169 The picture of human, taught for the first time by Aristotle, still required about twice four hundred years-- from the fourth pre-Christian to the fourth post-Christian century-- 170 before it became so far the common possession of people that the Church Father Augustine (354-430) could base his teaching on it-- a teaching which moulded human's outlook on the self for the coming centuries right up to our own time.

171 The following passage from Augustine's Confessions shows clearly how he was compelled to think about the nature of the little child: 172 'This age, whereof I have no remembrance, which I take on others' words, and guess from other infants that I have passed, true though the guess be, I am yet loath to count in this life of mine which I live in this world. 173 For no less than that which I lived in my mother's womb, is it hid from me in the shadows of forgetfulness. 174 But if I was shapen in iniquity and in sin my mother did conceive me, where, I beseech thee, O my God, where, Lord, or when, was I thy servant guiltless? 175 But lo! That period I pass by; and what have I to do with that of which I can recall no vestige?'

176 On the grounds of such experience, Augustine was unable to picture human's being in any other way than by seeing you, from the first moment of your life, as subject to the condition of the human race which resulted from the Fall. 177 Thus he exclaims in his Confessions: 'Before Thee, O God, no-one is free from sin, not even the child which has lived but a single day on the earth.' 178 In so far as there was any question of the soul's arising from this fallen state, it was deemed unable to attain this by any effort of its own, but to depend on the gifts of grace which the Church was able to dispense through the Sacraments.

179 Compare with this the present-day scientific conception of human nature, as it dominates the thought of specialist and layman alike. 180 Here human appears, both in body

and soul, as a sum of inherited characteristics, of characteristics, that is to say, which have been passed on by way of sexual propagation and gradually emerge into full manifestation as the individual grows up. 181 Apart from this inherited predestination the soul is held to present itself, in Locke's classical phrase, as a tabula-rasa upon which are stamped all manner of external impressions.

182 The similarity between this modern picture of human and the earlier theological one is striking. 183 In both cases the central assumption is that human development from child to adult consists in the unfolding of certain inherited characteristics which are capable of further specific modification under influences proceeding from outside. 184 The only difference between the two pictures is that in the modern one the concepts of heredity and adaptation have been formed without special application to the ethical characteristics of the soul.

185 It is clear that from both Augustine's and the modern scientific viewpoint there is no sense in requiring-- as Reid did-- those who seek the truth about themselves and the world to recover a condition which had been theirs as children. 186 Nor from this point of view is there any justification to call on a Common Sense, innate in human, to sit in judgment on the philosophical efforts of the adult reason.

187 That even in the days of Augustine the original conception of human nature had not disappeared entirely, is shown by the appearance of Augustine's opponent Pelagius, called the 'arch-heretic'. 188 To consider him at this point in our discussion will prove helpful for our understanding of Reid's historic position in the modern age.

189 What interests us here in Pelagius's doctrine (leaving aside all questions concerning the meaning of the Sacraments, etc.), is the picture of human which must have lived in him for him to teach as he did.

190 Leaving his Irish-Scottish homeland and arriving about the year 400 in Rome, where on account of the unusual purity of his being he soon came to be held

in the highest esteem, 191 Pelagius found himself obliged to come out publicly against Augustine, for he felt that Augustine's teachings denied all free will to human. 192 In the purely passive surrender of human to the will of God, as Augustine taught it, he could not but see danger for the future development of Christian humanity. 193 How radically he diverged from Augustine in his view of human we may see from such of his leading thoughts as follow: 'Each human begins own life in the same condition as Adam.' 194 'All good or evil for which in life we are deserving of praise or blame is done by ourselves and is not born with us.' 195 'Before the personal will of human comes into action there is nothing in you but what God has placed there.' 196 'It is therefore left to the free will of human whether you falls into sin, as also whether through following Christ you raises yourself out of it again.' 197 Pelagius could think in this way because he came from a part of Europe where the older form of human memory, already at that time almost extinct in the South, was in some degree still active. 198 For him it was therefore a matter of direct experience that the development of human from childhood onwards was connected with a diminution of certain original capacities of the soul. 199 Yet he was so far a child of his age as to be no longer capable of seeing whence these capacities originated.

200 To provide the necessary corrective to Augustine's doctrine of inheritance, Pelagius would have had to be able to see in the first years of life both a beginning of the earthly and a termination of the pre-earthly existence of the soul. 201 The imperfections of his picture of human, however, led him to underestimate, even to deny, the significance of heredity and so of original sin in human life. 202 For an age which no longer had any direct experience of the soul's pre-natal life, the doctrines of Augustine were undoubtedly more appropriate than those of Pelagius; Augustine was in fact the more modern of the two.

203 And now, if we move forward a dozen centuries and compare

Thomas Reid and Immanuel Kant from this same point of view, we find the same conception of human again triumphant. 204 But there is an essential difference: Kant carried all before him because he based himself on an age-old view of human nature, 205 whereas Reid, uncomprehended up to our own day, pointed to a picture of human only just then dawning on the horizon of the future. 206 Just as through Pelagius there sounded something like a last call to European humanity not to forget the cosmic nature of the soul, so through Reid the memory of this nature announced its first faint renewal. 207 It is common to both that their voices lacked the clarity to make themselves heard among the other voices of their times; 208 and with both the reason was the same: neither could perceive in fullness-- the one no longer, the other not yet-- the picture of human which ensouled their ideas.

209 The certainty of Reid's philosophical instinct, if such an expression be allowed, and at the same time his tragic limitations, due to an inability fully to understand the origin of this instinct, 210 come out clearly in the battle he waged against the 'idea' as his immediate predecessors understood it. 211 We know that Plato introduced this word into the philosophical language of humankind. 212 In Greek Î¹Î´ÎÎ± (from Î¹Î´Îµá¿‘Î½, to see) means something of which one knows that it exists, because one sees it. 213 It was therefore possible to use the word 'to see' as Plato did, because in his day it covered both sensible and super-sensible perception. 214 For Plato, knowing consisted in the soul's raising itself to perceiving the objective, world-forming IDEAS, and this action comprised at the same time a recollection of what the soul had seen while it lived, as an Idea among Ideas, before its appearance on earth.

215 As long as Plato's philosophy continued to shape their thought, people went on speaking more or less traditionally of Ideas as real super-sensible beings. 216 When, however, the Aristotelian mode of thinking superseded the Platonic, the term 'Idea' ceased to be used in its original sense; 217 so much so that, when Locke and other

modern philosophers resorted to it in order to describe the content of the mind, they did so in complete obliviousness of its first significance.

218 It is thus that in modern philosophy, and finally in ordinary modern usage, 'idea' came to be a word with many meanings. 219 Sometimes it signifies a sense-impression, sometimes a mental representation, sometimes the thought, concept or essential nature of a thing. 220 The only thing common to these various meanings is an underlying implication that an idea is a purely subjective item in human consciousness, without any assured correspondence to anything outside.

221 It was against this view of the idea that Reid took the field, going so far as to label the philosophy holding it the 'ideal system'. 222 He failed to see, however, that in attacking the abstract use of the term he was actually in a position to restore to it its original, genuine meaning. 223 If, instead of simply throwing the word overboard, he had been able to make use of it in its real meaning, he would have expressed himself with far greater exactitude and consistency. 224 He was prevented from doing this by his apparent ignorance of the earlier Greek philosophers, Plato included. 225 All he seems to have known of their teachings came from inferior, second-hand reports of a later and already decadent period.

226 There are two historic personalities, both in England, who witness to the fact that the emergence of Reid's philosophy on the stage of history was by no means an accidental event 227 but that it represents a symptom of a general reappearance of the long-forgotten picture of human, in which birth no more than death sets up an absolute limit to human existence. 228 They are Thomas Traherne (1638-74) and William Wordsworth (1770-1850).

229 Wordsworth's work and character are so well known that there is no need to speak of them here in detail. 230 For our purpose we shall pay special attention only to his '*Ode on Intimations of Immortality from Recollections of Early Childhood*', 231 where he shows himself in possession of a

memory (at any rate at the time when he wrote the poem) of the pre-natal origin of the soul, and of a capacity for experiencing, at certain moments, the frontier which the soul crosses at birth.

232 If, despite the widespread familiarity of the Ode, we here quote certain passages from it, we do so because, like many similar things, it has fallen a victim to the intellectualism of our time in being regarded merely as a piece of poetic fantasy. 233 We shall take the poet's words as literally as he himself uttered them. We read:

'Our birth is but a sleep and a forgetting:
The Soul that rises with us, our life's Star,
Hath had elsewhere its setting,
And cometh from afar:
Not in entire forgetfulness,
And not in utter nakedness,
But trailing clouds of glory do we come
From God who is our home:
Heaven lies about us in our infancy!

234 Shades of the prison house begin to close
Upon the growing Boy.
But he beholds the light, and whence it flows,
He sees it in his joy;
The Youth, who daily farther from the east
Must travel, still is Nature's Priest,
And by the vision splendid
Is on his way attended."

235 And later:

'Hence in a season of calm weather
Though inland far we be,
Our Souls have sight of that immortal sea
Which brought us hither,
Can in a moment travel thither,
And see the Children sport upon the shore,
And hear the mighty waters rolling evermore."

236 The fact that Wordsworth in his later years gave no further indication of such experiences need not prevent us from taking quite literally what he says here. 237 The truth is that an original faculty faded away with increasing age, somewhat as happened with Reid when he could no longer continue his philosophical work

along its original lines. 238 Wordsworth's Ode is the testament of the childhood forces still persisting but already declining within him; 239 it is significant that he set it down in about the same year of life (his thirty-sixth) as that in which Traherne died and in which Goethe, seeking renewal of his being, took flight to Italy.

240 Of Traherne, too, we shall say here only as much as our present consideration and the further aims of this book require. 241 We cannot concern ourselves with the remarkable events which led, half a century ago, to the discovery and identification of his long-lost writings by Bertram Dobell. 242 Nor can we deal with the details of the eventful life and remarkable spiritual development of this contemporary of the Civil War. 243 These matters are dealt with in Dobell's introduction to his edition of Traherne's poems, as also by Gladys I. Wade in her work, Thomas Traherne. 244 Our gratitude for the labours of these two writers by which they have provided humankind with the knowledge of the character and the work of this unique personality cannot hinder us, 245 however, from stating that both were prevented by the premises of their own view of the world from rightly estimating that side of Traherne which is important for us in this book, and with which we shall specially concern ourselves in the following pages.

246 Later in this chapter we shall discuss Dobell's philosophical misinterpretation of Traherne, to which he fell victim because he maintained his accustomed spectator standpoint in regard to his object of study. 247 Miss Wade has, indeed, been able to pay the right tribute to Traherne, the mystic, whose inner (and also outer) biography she was able to detect by taking seriously Traherne's indications concerning his mystical development. 248 Her mind, however, was too rigidly focused on this side of Traherne's life-- his self-training by an iron inner discipline and his toilsome ascent from the experience of Nothingness to a state of Beatific Vision. 249 This fact, combined with her disinclination to overcome the Augustinian picture of human in herself, prevented her

from taking Traherne equally seriously 250 where he speaks as one who is endowed with a never interrupted memory of his primeval cosmic consciousness-- 251 notwithstanding the fact that Traherne himself has pointed to this side of his nature as the most significant for his fellow-men.

252 Of the two works of Traherne which Dobell rescued from oblivion, on both of which we shall draw for our exposition, one contains his poems, the other his prose writings. The title of the latter is Centuries of Meditations. 253 The title page of one of the two manuscripts containing the collection of the poetical writings introduces these as Poems of Felicity, Containing Divine Reflections on the Native Objects of an Infant-Eye. 254 As regards the title '*Centuries of Meditations*' we are ignorant of the meaning Traherne may have attached to it, and what he meant by calling the four parts of the book, 'First', 'Second', etc., Century. 255 The book itself represents a manual of devotion for meditative study by the reader.

256 Let our first quotation be one from the opening paragraph of the third 'Century' in which Traherne introduces himself as the bearer of certain uncommon powers of memory and, arising from these powers, a particular mission as a teacher:

257 'Those pure and virgin apprehensions I had from the womb, and that divine light wherewith I was born are the best unto this day, wherein I can see the Universe. 258 By the gift of God they attended me into the world, and by His special favour I remember them till now. 259 Verily they seem the greatest gifts His wisdom could bestow, for without them all other gifts had been dead and vain. 260 They are unattainable by books, and therefore I will teach them by experience.' 261 The picture thus remaining with him of his nature of soul in his earliest years on earth he describes as follows:

262 'Certainly Adam in Paradise had not more sweet and curious apprehensions of the world, than I when I was a child. 263 All appeared new, and strange at first, inexpressibly rare and delightful

and beautiful. 264 I was a little stranger, which at my entrance into the world was saluted and surrounded with innumerable joys. 265 My knowledge was Divine. I knew by intuition those things which since my Apostacy, I collected again by the highest reason. 266 I was entertained like an Angel with the works of God in their splendour and glory, I saw all in the peace of Eden; 267 Heaven and Earth did sing my Creator's praises, and could not make more melody to Adam, than to me. All Time was Eternity, and a perpetual Sabbath. 268 Is it not strange, that an infant should be the heir of the whole world, and see those mysteries which the books of the learned never unfold?'

269 In a different form the same experience comes to expression in the opening lines of Traherne's poem, Wonder:

'How like an Angel came I down!
How bright are all things here I
When first among his Works I did appear
O how their GLORY did me crown!
The World resembled his ETERNITIE,
In which my Soul did Walk;
And evry Thing that I did see
Did with me talk.'

270 The picture of human thus sketched by Traherne is as close to Reid's as it is remote from Augustine's. 271 This remoteness comes plainly to expression in the way Traherne and Augustine regard the summons of Christ to His disciples to become as little children, 272 a summons to which Reid was led, as we have seen, on purely philosophical grounds. 273 Let us first of all recall the words of Christ as recorded by Matthew in his 18th and 19th chapters: 'And Jesus called a little child unto him, and set him in the midst of them, 274 and said: Verily I say unto you, except ye be converted, and become as little children, ye shall not enter into the kingdom of Heaven. 275 Whosoever therefore shall humble the self as this little child, the same is the greatest in the kingdom of Heaven.' (xviii, 2-4.) 276 'Suffer the little children and forbid them not to come unto me: for of such is the kingdom of Heaven.' (xix, 14.)

277 Augustine refers to these words when he concludes that examination of his childhood memories which he undertook in order to prove the depravity of the soul from its first day on earth. 278 He says: 'In the littleness of children didst Thou, our king, give us a symbol of humility when Thou didst say: Of such is the kingdom of Heaven.'

279 If we glance back from what Augustine says here to the original passages in the Gospel just quoted, we see what a remarkable alteration he makes. 280 Of the first passage only the last sentence is taken, and this in Augustine's mind is fused into one with the second passage. 281 Thereby the admonition of Christ through one's own effort to become as one once was as a child disappears completely. 282 The whole passage thus takes on a meaning corresponding to that passive attitude to the divine will inculcated by Augustine and opposed by Pelagius, 283 and it is in this sense that the words of Christ have sunk into the consciousness of Western Christianity and are usually taken to-day.

284 We may see how differently this injunction of Christ lived in Traherne's consciousness from the following passage out of his Centuries:

285 'Our Saviour's meaning, when He said, ye must be born again and become a little child that will enter into the Kingdom of Heaven, is deeper far than is generally believed. 286 It is not only in a careless reliance upon Divine Providence, that we are to become little children, or in the feebleness and shortness of our anger and simplicity of our passions, but in the peace and purity of all our soul. 287 Which purity also is a deeper thing than is commonly apprehended.'

288 With Traherne also the passage in question has been fused together with another utterance of Christ, from John's account of Christ's conversation with Nicodemus:

289 'Verily, verily I say unto you, except a human be born again, you cannot see the Kingdom of God.' (John iii, 3.)

290 What conception of the infant condition of human must have

existed in a soul for it to unite these two passages from the Gospels in this way? 291 Whereas for Augustine it is because of its small stature and helplessness that the child becomes a symbol for the spiritual smallness and helplessness of human as such, compared with the overwhelming power of the divine King, 292 for Traherne it is the child's nearness to God which is most present to him, and which must be regained by the person who strives for inner perfection.

293 Traherne could bear in himself such a picture of human's infancy because, as he himself emphasises, he was in possession of an unbroken memory of the experiences which the soul enjoys before it awakens to earthly sense-perception. 294 The following passage from the poem, My Spirit, gives a detailed picture of the early state in which the soul has experiences and perceptions quite different from those of its later life. 295 We may recall Reid's indication of how the child receives the natural language of things.

296 'An Object, if it were before
Mine Ey, was by Dame Nature's Law
Within my Soul: Her Store
Was all at once within me; all her Treasures
Were my immediat and internal Pleasures;
Substantial Joys, which did inform my Mind.

297 '... I could not tell
Whether the Things did there
Themselvs appear,
Which in my Spirit truly seem'd to dwell:
Or whether my conforming Mind
Were not ev'n all that therein shin'd.'

298 Further detail is added to this picture by the description, given in the poem The Praeparative, of the soul's non-experience of the body at that early stage. 299 The description is unmistakably one of an experience during the time between conception and birth.

300 'My Body being dead, my Limbs unknown;
Before I skill'd to prize
Those living Stars, mine Eys;

MATTER

Before or Tongue or Cheeks I call'd mine own,
Before I knew these Hands were mine,
Or that my Sinews did my Members join;
When neither Nostril, Foot, nor Ear,
As yet could be discerned or did appear;
I was within
A House I knew not; newly cloath'd with Skin.

301 Then was my Soul my only All to me,
A living endless Ey,
Scarce bounded with the Sky,
Whose Power, and Act, and Essence was to see;
I was an inward Sphere of Light,
Or an interminable Orb of Sight,
Exceeding that which makes the Days,
A vital Sun that shed abroad its Rays:
All Life, all Sense,
A naked, simple, pure Intelligence."

302 In the stanza following upon this, Traherne makes a statement which is of particular importance in the context of our present discussion. 303 After some additional description of the absence of all bodily needs he says: 'Without disturbance then I did receive The true Ideas of all Things' 304 The manuscript of this poem shows a small alteration in Traherne's hand in the second of these two lines. 305 Where we now read 'true Ideas', there originally stood 'fair Ideas'. 'Fair' described Traherne's experience as he immediately remembered it; 306 the later alteration to 'true' shows how well aware he was that his contemporaries might miss what he meant by 'Idea', 307 through taking it in the sense that had already become customary in his time, namely, as a mere product of human's own mental activity.

308 This precaution, however, has not saved Traherne from being misinterpreted in our own day in precisely the way he feared--indeed, by no less a person than his own discoverer, Dobell. 309 It is the symptomatic character of this misinterpretation which prompts us to deal with it here.

310 In his attempt to classify the philosophical mode of thought

behind Traherne's writings, Dobell, to his own amazement, comes to the conclusion that Traherne had anticipated Bishop Berkeley (1684-1753). 311 They seemed to him so alike that he does not hesitate to call Traherne a 'Berkeleyan before Berkeley was born'. 312 In proof of this he refers to the poems, The Praeparative and My Spirit, and drawing special attention to its two concluding lines. 313 Regarding this he says: 'I am much mistaken if the theory of non-existence of independent matter, which is the essence of Berkeley's system, is not to be found in this poem. 314 The thought that the whole exterior universe is not really a thing apart from and independent of human's consciousness of it, but something which exists only as it is perceived, is undeniably found in My Spirit:

315 The reader who has followed our exposition in the earlier parts of this chapter can be in no doubt that, to find a philosophy similar to Traherne's, he must look for it in Reid and not in Berkeley. 316 Reid himself rightly placed Berkeley amongst the representatives of the 'ideal system' of thought. 317 For Berkeley's philosophy represents an effort of the onlooker-consciousness, unable as it was to arrive at certainty regarding the objective existence of a material world outside itself, to secure recognition for an objective Self behind the flux of mental phenomena. 318 Berkeley hoped to do this by supposing that the world, including God, consists of nothing but 'idea'-creating minds, operating like the human mind as human perceives it. 319 His world picture, based (as is well known) entirely on optical experiences, is the perfect example of a philosophy contrived by the one-eyed, colourblind world-spectator.

320 We shall understand what in Traherne's descriptions reminded Dobell of Berkeley, if we take into account the connexion of the soul with the body at the time when, 321 according to Traherne, it still enjoys the untroubled perception of the true, the light-filled, Ideas of things.

322 In this condition the soul has only a dim and undifferentiated awareness of its connexion with a spatially limited body-- 'I was

within a house I knew not, newly clothed with skin'-- 323 and it certainly knows nothing at all of the body as an instrument, through which the will can be exercised in an earthly-spatial way-- 'My body being dead, my limbs unknown'. 324 Instead of this, the soul experiences itself simply as a super-sensible sense-organ and as such united with the far spaces of the universe-- 325 'Before I skilled to prize those living stars, mine eyes. … Then was my soul my only All to me, a living endless eye, scarce bounded with the sky'. 326 At the time when the soul has experiences of the kind described by Traherne, it is in a condition in which, as yet, no active contact has been established between itself and the physical matter of the body and thereby with gravity. 327 Hence there is truth in the picture which Traherne thus sketches from actual memory. The same cannot be said of Berkeley's world-picture. 328 The fact that both resemble each other in certain features need not surprise us, seeing that Berkeley's picture is, in its own way, a pure 'eye-picture' of the world. As such, however, it is an illusion-- 329 for it is intended for a state of human for which it is not suited, namely for adult human going upright on the earth, directing your deeds within its material realm, and in this way fashioning your own destiny.

330 Indeed, compared with Berkeley's eye-picture of the world, that of Reid is in every respect a 'limb-picture'. 331 For where he seeks for the origin of our naÃ¯ve assurance that a real material world exists, there he reverts-- 332 guided by his common sense-- to the experiences available to the soul through the fact that the limbs of the body meet with the resistant matter of the world. 333 And whenever he turns to the various senses in his search, it is always the will-activity of the soul within the sense he is investigating-- and so the limb-nature within it-- to which he first turns his attention. 334 Because, unlike Berkeley, he takes into account the experiences undergone by the soul when it leaves behind its primal condition, 335 Reid does not fall into illusion, but discovers a fundamental truth concerning the nature of the

world-picture experienced by human in your adult age. 336 This, in turn, enables him to discover the nature of human's world picture in early childhood and to recognise the importance of recovering it in later life as a foundation for a true philosophy.

337 Assuredly, the philosopher who discovered that we must become as little children again if we would be philosophers, is the one to whom we may relate Traherne, but not Berkeley. 338 And if we wish to speak of Traherne, as Dobell tried to do, we speak correctly only if we call him a 'Reidean before Reid was born'.

339 A little more than a hundred years after Thomas Traherne taught his fellow-people 'from experience' that there is an original condition of human's soul, 340 before it is yet able to prize 'those living stars, mine eyes', in which it is endowed with the faculty to see 'the true (fair) Ideas of all things', 341 Goethe was led to the realisation that he had achieved the possibility of 'seeing Ideas with the very eyes'. 342 Although he was himself not aware of it, the conception of the Idea was at this moment restored through him to its true and original Platonic significance.

343 The present chapter has shown us how this conception of the Idea is bound up with the view that is held of the relationship between human nature in early childhood and human nature in later life. 344 We have seen that, when Plato introduced the term Idea as an expression for spiritual entities having a real and independent existence, people were still in possession of some recollection of their own pre-earthly existence. 345 We then found Traherne saying from his recollections that in the original form of human's consciousness your soul is endowed with the faculty of seeing 'true' Ideas, 346 and we found Reid on similar grounds fighting the significance which the term 'idea' had assumed under his predecessors. 347 By their side we see Goethe as one in whom the faculty of seeing Ideas appears for the first time in adult human as a result of a systematic training of observation and thought. 348 If our view of the interdependence of the Platonic conception of the Idea

with the picture human has of the self is seen rightly, then Goethe must have been the bearer of such a picture. 349 Our expectation is shown to be right by the following two passages from Goethe's autobiography, Truth and Fiction.

350 In that part of his life story where Goethe concludes the report of the first period of his childhood, he writes:

'Who is able to speak worthily of the fullness of childhood? 351 We cannot behold the little creatures which flit about before us otherwise than with delight, nay, with admiration; 352 for they generally promise more than they perform and it seems that Nature, among the other roguish tricks that She plays us, here also especially designs to make sport of us. 353 The first organs She bestows upon children coming into the world, are adapted to the nearest immediate condition of the creature, which, unassuming and artless, makes use of them in the readiest way for its present purposes. 354 The child, considered in and for itself, with its equals, and in relations suited to its powers, seems so intelligent and rational, and at the same time so easy, cheerful and clever, that one can hardly wish it further cultivation. 355 If children grew up according to early indications, we should have nothing but geniuses.'

356 We find further evidence in Goethe's account of an event in his seventh year, which shows how deeply his soul was filled at that time with the knowledge of its kinship with the realm from which Nature Herself receives its existence. 357 This knowledge led him to approach the 'great God of Nature' through an act of ritual conceived by himself. 358 The boy took a four-sectioned music stand and arranged on it all kinds of natural specimens, minerals and the like, until the whole formed a kind of pyramidal altar. 359 On the top of this pyramid he placed some fumigating candles, the burning of which was to represent the 'upward yearning of the soul for its God'. 360 In order to give Nature Herself an active part in the ritual, he contrived to kindle the candles by focusing upon them through a magnifying-glass the light of the rising sun. 361 Before this symbol of the unity of the soul with the

divine in Nature the boy then paid his devotions. 'Unity of the soul with the divine in Nature'-- 362 this was what lived vividly as a conviction in the seven-year-old boy, impelling him to act as 'Nature's priest' (Wordsworth). 363 The same impulse, in a metamorphosed form, impelled the adult to go out in quest of an understanding of Nature which, as Traherne put it, was to bring back through highest reason what once had been one's own by way of primeval intuition.

ALWAYS STAND BY FORM

Ernst Lehrs

7 Immediacy of approach to certain essentials of Nature as a result of their religious or artistic experience of the sense-world, is the characteristic of two more representatives of British cultural life. 2 They are Luke Howard (1772-1864) and John Ruskin (1819-1900), both true readers in the book of Nature. 3 Like those discussed in the previous chapter they can be of especial help to us in our attempt to establish an up-to-date method of apprehending Nature's phenomena through reading them.

4 At the same time we shall find ourselves led into another sphere of Goethe's scientific work. For we cannot properly discuss Howard without recognising the importance of his findings for Goethe's meteorological studies 5 or without referring to the personal connexion between the two men arising out of their common interest and similar approach to Nature. 6 We shall thus come as a matter of course to speak of Goethe's thoughts about meteorology, and this again will give opportunity to introduce a leading concept of Goethean science in addition to those brought forward already.

7 Of Ruskin only so much will appear in the present chapter as is necessary to show him as an exemplary reader in the book of Nature. He will then be a more or less permanent companion in our investigations.

8 The following words of Ruskin from The Queen of the Air reveal him at once as a true reader in the book of Nature:

9 'Over the entire surface of the earth and its waters, as influenced by the power of the air under solar light, there is developed a series of changing forms, in clouds, plants and animals, all of which have reference in their action, or nature, to the human intelligence that perceives them.'

10 Here Ruskin in an entirely Goethean way points to form in Nature as the element in Her that speaks to human intelligence-- 11 meaning by form, as other utterances of his show, all those qualities through which the natural object under observation reveals itself to our senses as a whole.

12 By virtue of his pictorial-dynamic way of regarding Nature, Ruskin was quite clear that the scientists' one-sided seeking after external forces and the mathematically calculable interplay between them can never lead to a comprehension of life in Nature. 13 For in such a search human loses sight of the real signature of life: form as a dynamic element. 14 Accordingly, in his Ethics of the Dust, Ruskin does not answer the question: 'What is Life?' with a scientific explanation, but with the laconic injunction: 'Always stand by Form against Force.' 15 This he later enlarges pictorially in the words: 'Discern the moulding hand of the potter commanding the clay from the merely beating foot as it turns the wheel.'

16 In thus opposing form and force to each other, Ruskin is actually referring to two kinds of forces. 17 There exist those forces which resemble the potter's foot in producing mere numerically regulated movements (so that this part of the potter's activity can be replaced by a power machine), 18 and others, which like the potter's hand, strive for a certain end and so in the process create definite forms. 19 Ruskin goes a step further still in The Queen of the Air, where he speaks of selective order as a mark of the spirit:

20 'It does not merely crystallise indefinite masses, but it gives to limited portions of matter the power of gathering, selectively, other elements proper to them, and binding these elements into their own peculiar and adopted form. ...

21 'For the mere force of junction is not spirit, but the power that

catches out of chaos, charcoal, water, lime and whatnot, and fastens them into given form, is properly called "spirit"; 22 and we shall not diminish, but strengthen our cognition of this creative energy by recognising its presence in lower states of matter than our own.'

23 When Ruskin wrote this passage, he could count on a certain measure of agreement from his contemporaries that the essence of human is spirit, though certainly without any very exact notion being implied. 24 This persuaded him to fight on behalf of the spirit, lest its activity on the lower levels of Nature should not be duly acknowledged. 25 To-day, when the purely physical conception of Nature has laid hold of the entire human, Ruskin might have given his thought the following turn: 26 '... and we shall certainly attain to no real insight into this creative force (of the spirit) at the level of human, unless we win the capacity to recognise its activity in lower states of matter.'

27 What Ruskin is really pointing towards is the very thing for which Goethe formed the concept 'type'. 28 And just as Ruskin, like Goethe, recognised the signature of the spirit in the material processes which work towards a goal, so he counted as another such signature what Goethe called Steigerung, though certainly without forming such a universally valid idea of it:

29 'The Spirit in the plant-- that is to say, its power of gathering dead matter out of the wreck round it, and shaping it into its own chosen shape-- is of course strongest in the moment of flowering, for it then not only gathers, but forms, with the greatest energy.' 30 It is characteristic of Ruskin's conception of the relationship between human's mind and Nature that he added: 31 'And where this life is in it at full power, its form becomes invested with aspects that are chiefly delightful to our own senses.'

32 Obviously, a mind capable of looking at Nature in this way could not accept such a picture of evolution as was put forward by Ruskin's contemporary, Darwin. 33 So we find Ruskin, in The Queen of the Air, opposing the Darwinistic conception of the

preservation of the species as the driving factor in the life of Nature: 34 'With respect to plants as animals, we are wrong in speaking as if the object of life were only the bequeathing of itself. 35 The flower is the end and proper object of the seeds, not the seed of the flower. 36 The reason for the seed is that flowers may be, not the reason of flowers that seeds may be. 37 The flower itself is the creature which the spirit makes; only, in connection with its perfectedness, is placed the giving birth to its successor.'

38 For Ruskin the true meaning of life in all its stages lay not in the maintenance of physical continuity from generation to generation, but in the ever-renewed, ever more enhanced revelation of the spirit.

39 He was never for a moment in doubt regarding the inevitable effect of such an evolutionary theory as Darwin's on the general social attitude of humanity. 40 Humans would be led, he realised, to see themselves as the accidental products of an animal nature based on the struggle for existence and the preservation of the species. 41 Enough has been said to stamp Ruskin as a reader in the book of Nature, capable of deciphering the signature of the spirit in the phenomena of the sense-world.

42 Outwardly different from Ruskin's and yet spiritually comparable, is the contribution made by his older contemporary, Luke Howard, to the foundation of a science of Nature based on intuition. 43 Whereas Ruskin throws out a multitude of aphoristic utterances about many different aspects of Nature, which will provide us with further starting-points for our own observation and thought, 44 Howard is concerned with a single sphere of phenomena, that of cloud formation. On the other hand, his contribution consists of a definite discovery which he himself methodically and consciously achieved, 45 and it is the content of this discovery, together with the method of research leading to it, which will supply us ever and again with a model for our own procedure. 46 At the same time, as we have indicated, he will help us to become familiar with another side of Goethe, and to widen our

knowledge of the basic scientific concepts formed by him.

47 Anyone interested to-day in weather phenomena is acquainted with the terms used in cloud classification-- Cirrus, Cumulus, Stratus, and Nimbus. 48 These have come so far into general use that it is not easy to realise that, until Howard's paper, On the Modification of Clouds, appeared in 1803, no names for classifying clouds were available. 49 Superficially, it may seem that Howard had done nothing more than science has so often done in grouping and classifying and naming the contents of Nature. 50 In fact, however, he did something essentially different.

In the introduction to his essay, Howard describes the motives which led him to devote himself to a study of meteorological phenomena:

51 'It is the frequent observation of the countenance of the sky, and of its connexion with the present and ensuing phenomena, that constitutes the ancient and popular meteorology. 52 The want of this branch of knowledge renders the prediction of the philosopher-- who in attending his instruments may be said to examine the pulse of the atmosphere,-- less generally successful than those of the weather-wise mariners and husbandmen.'

53 When he thus speaks of studying 'the countenance of the sky', Howard is not using a mere form of speech; he is exactly describing his own procedure, as he shows when he proceeds to justify it as a means to scientific knowledge. 54 The clouds with their ever-moving, ever-changing forms are not, he says, to be regarded as the mere 'sport of the winds', 55 nor is their existence 'the mere result of the condensation of vapour in the masses of the atmosphere which they occupy'. 56 What comes to view in them is identical, in its own realm, with what the changing expression of the human face reveals of 'a person's state of mind or body'. 57 It would hardly be possible to represent oneself more clearly as a genuine reader in the book of Nature than by such words. 58 What is it but Ruskin's 'Stand by Form against Force' that

Howard is here saying in his own way?

59 Before entering into a further description of Howard's system, we must make clear why we disregard the fact that modern meteorology has developed the scale of cloud-formation far beyond Howard, and why we shall keep to his own fourfold scale.

60 It is characteristic of Goethe that, on becoming acquainted with Howard's work, he at once gave a warning against subdividing his scale without limit. 61 Goethe foresaw that the attempt to insert too many transitory forms between Howard's chief types would result only in obscuring that view of the essentials which Howard's original classification had opened up. 62 Obviously, for a science based on mere onlooking there is no objection to breaking up an established system into ever more subdivisions in order to keep it in line with an increasingly detailed outer observation. 63 This, indeed, modern meteorology has done with Howard's system, with the result that, to-day, the total scale is made up of ten different stages of cloud-formation.

64 Valuable as this tenfold scale may be for certain practical purposes, it must be ignored by one who realises that through Howard's fourfold scale Nature Herself speaks to human's intuitive judgment. 65 Let us, therefore, turn to Howard's discovery, undisturbed by the extension to which modern meteorology has subjected it.

66 Luke Howard, a chemist by profession, knew well how to value the results of scientific knowledge above traditional folk-knowledge. 67 He saw the superiority of scientifically acquired knowledge in the fact that it was universally communicable, whereas folk-wisdom is bound up with the personality of its bearer, his individual observations and his memory of them. 68 Nevertheless, the increasing mathematising of science, including his own branch of it, gave him great concern, for he could not regard it as helpful in the true progress of human's understanding of Nature. 69 Accordingly, he sought for a method of observation in which the practice of 'the weatherwise mariner and husbandman' could be

raised to the level of scientific procedure. 70 To this end he studied the changing phenomena of the sky for many years, until he was able so to read its play of features that it disclosed to him the archetypal forms of cloud-formation underlying all change. 71 To these he gave the now well-known names (in Latin, so that they might be internationally = comprehensible):

Cirrus: Parallel, flexuous or divergent fibres extensible in any and all directions.

72 Cumulus: Convex or conical heaps, increasing upwards from a horizontal base.

Stratus: A widely extended, continuous, horizontal sheet, increasing from below.

Nimbus: The rain cloud.

73 Let us, on the background of Howard's brief definitions, try to form a more exact picture of the atmospheric dynamics at work in each of the stages he describes.

74 Among the three formations of cirrus, cumulus and stratus, the cumulus has a special place as representing in the most actual sense what is meant by the term 'cloud'. 75 The reason is that both cirrus and stratus have characteristics which in one or the other direction tend away from the pure realm of atmospheric cloud-formation. 76 In the stratus, the atmospheric vapour is gathered into a horizontal, relatively arched layer around the earth, and so anticipates the actual water covering below which extends spherically around the earth's centre. 77 Thus the stratus arranges itself in a direction which is already conditioned by the earth's field of gravity. 78 In the language of physics, the stratus forms an equipotential surface in the gravitational field permeating the earth's atmosphere.

79 As the exact opposite of this we have the cirrus. If in the stratus the form ceases to consist of distinct particulars, because the entire cloud-mass runs together into a single layer, 80 in the cirrus the form begins to vanish before our eyes, because it dissolves into the surrounding atmospheric space. 81 In the cirrus there is present a tendency to expand; in the stratus to contract. 82 Between the two, the cumulus, even viewed simply as a form-type, represents an exact

mean. 83 In how densely mounded a shape does the majestically towering cumulus appear before us, and yet how buoyantly it hovers aloft in the heights! 84 If one ever comes into the midst of a cumulus cloud in the mountains, one sees how its myriads of single particles are in ceaseless movement. 85 And yet the whole remains stationary, on windless days preserving its form unchanged for hours. 86 More recent meteorological research has established that in many cumulus forms the entire mass is in constant rotation, although seen from outside, it appears as a stable, unvarying shape. 87 Nowhere in Nature may the supremacy of form over matter be so vividly observed as in the cumulus cloud. 88 And the forms of the cumuli themselves tell us in manifold metamorphoses of a state of equilibrium between expansive and contractive tendencies within the atmosphere.

89 Our description of the three cloud-types of cirrus, cumulus and stratus, makes it clear that we have to do with a self-contained symmetrical system of forms, 90 within which the two outer, dynamically regarded, represent the extreme tendencies of expansion and contraction, whilst in the middle forms these are held more or less in balance. 91 By adding Howard's nimbus formation to this system, we destroy its symmetry. 92 Actually, in the nimbus we have cloud in such a condition that it ceases to be an atmospheric phenomenon in any real sense of the word; 93 for it now breaks up into single drops of water, each of which, under the pull of gravity, makes its own independent way to the earth. 94 The symmetry is restored as soon as we realise that the nimbus, as a frontier stage below the stratus, has a counterpart in a corresponding frontier stage above the cirrus. 95 To provide insight into this upper frontier stage, of which neither Howard nor Goethe was at that time in a position to develop a clear enough conception to deal with it scientifically, is one of the aims of this book.

96 In order to understand what prompted Goethe to accept, as he did, Howard's classification and terminology at first glance, and what persuaded him to make

himself its eloquent herald, 97 we must note from what point Goethe's labours for a natural understanding of Nature had originated.

98 In his History of my Botanical Studies Goethe mentions, besides Shakespeare and Spinoza, Linnaeus as one who had most influenced his own development. 99 Concerning Linnaeus, however, this is to be understood in a negative sense. For when Goethe, himself searching for a way of bringing the confusing multiplicity of plant phenomena into a comprehensive system, met with the Linnaean system, 100 he was, despite his admiration for the thoroughness and ingenuity of Linnaeus's work, repelled by his method. 101 Thus by way of reaction, his thought was brought into its own creative movement: 102 'As I sought to take in his acute, ingenious analysis, his apt, appropriate, though often arbitrary laws, a cleft was set up in my inner nature: 103 what he sought to hold forcibly apart could not but strive for union according to the inmost need of my own being.'

104 Linnaeus's system agonised Goethe because it demanded from him 'to memorise a ready-made terminology, to hold in readiness a certain number of nouns and adjectives, 105 so as to be able, whenever any form was in question, to employ them in apt and skillful selection, and so to give it its characteristic designation and appropriate position.' 106 Such a procedure appeared to Goethe as a kind of mosaic, in which one ready-made piece is set next to another in order to produce out of a thousand details the semblance of a picture; and this was 'in a certain way repugnant' to him. 107 What Goethe awoke to when he met Linnaeus's attempt at systematising the plant kingdom was the old problem of whether the study of Nature should proceed from the parts to the whole or from the whole to the parts. 108 Seeing, therefore, how it became a question for Goethe, at the very beginning of his scientific studies, whether a natural classification of Nature's phenomena could be achieved, 109 we can understand why he was so overjoyed when,

towards the end of his life, in a field of observation which had meanwhile caught much of his interest, 110 he met with a classification which showed, down to the single names employed, that it had been read off from reality.

111 The following is a comprehensive description of Goethe's meteorological views, which he gave a few years before his death in one of his conversations with his secretary, Eckermann:

112 'I compare the earth and her hygrosphere to a great living being perpetually inhaling and exhaling. 113 If she inhales, she draws the hygrosphere to her, so that, coming near her surface, it is condensed to clouds and rain. 114 This state I call water-affirmative (WasserBejahung). Should it continue for an indefinite period, the earth would be drowned. 115 This the earth does not allow, but exhales again, and sends the watery vapours upwards, when they are dissipated through the whole space of the higher atmosphere. 116 These become so rarefied that not only does the sun penetrate them with its brilliancy, but the eternal darkness of infinite space is seen through them as a fresh blue. 117 This state of the atmosphere I call water-negative (WasserVerneinung). For just as, under the contrary influence, not only does water come profusely from above, but also the moisture of the earth cannot be dried and dissipated-- 118 so, on the contrary, in this state not only does no moisture come from above, but the damp of the earth itself flies upwards; 119 so that, if this should continue for an indefinite period, the earth, even if the sun did not shine, would be in danger of drying up.'

120 Goethe's notes of the results of his meteorological observations show how in them, too, he followed his principle of keeping strictly to the phenomenon. 121 His first concern is to bring the recorded measurements of weather phenomena into their proper order of significance. 122 To this end he compares measurements of atmospheric temperature and local density with barometric measurements. 123 He finds that the first two, being of a more local and accidental nature, have the

value of 'derived' phenomena, 124 whereas the variations in the atmosphere revealed by the barometer are the same over wide areas and therefore point to fundamental changes in the general conditions of the earth. 125 Measurements made regularly over long periods of time finally lead him to recognise in the barometric variations of atmospheric pressure the basic meteorological phenomenon.

126 In all this we find Goethe carefully guarding himself against 'explaining' these atmospheric changes by assuming some kind of purely mechanical cause, such as the accumulation of air-masses over a certain area or the like. 127 Just as little would he permit himself lightly to assume influences of an extra-terrestrial nature, such as those of the moon. 128 Not that he would have had anything against such things, if they had rested on genuine observation. 129 But his own observations, as far as he was able to carry them, told him simply that the atmosphere presses with greater or lesser intensity on the earth in more or less regular rhythms. 130 He was not abandoning the phenomenal sphere, however, when he said that these changes are results of the activity of earthly gravity, 131 or when he concluded from this that barometric variations were caused by variations in the intensity of the field of terrestrial gravity, whereby the earth sometimes drew the atmosphere to it with a stronger, and sometimes with a weaker, pull.

132 He was again not departing from the realm of the phenomenal when he looked round for other indications in Nature of such an alternation of drawing in and letting forth of air, and found them in the respiratory processes of animated beings. 133 To regard the earth as a merely physical structure was impossible for Goethe, for he could have done this only by leaving out of account the life visibly bound up with it. 134 Accordingly, barometric measurements became for him the sign of a breathing process carried out by the earth.

135 Alongside the alternating phases of contraction and expansion within the atmosphere,

Goethe placed the fact that atmospheric density decreases with height. 136 Observation of differences in cloud formation at different levels, of the boundary of snow formation, etc., led him to speak of different 'atmospheres', or of atmospheric circles or spheres, which when undisturbed are arranged concentrically round the earth. 137 Here also he saw, in space, phases of contraction alternating with phases of expansion.

138 At this point in our discussion it is necessary to introduce another leading concept of Goethean nature-observation, 139 which was for him-- as it will be for us-- of particular significance for carrying over the Goethean method of research from the organic into the inorganic realm of Nature. This is the concept of the ur-phenomenon (UrphÃ¤nomen). 140 In this latter realm, Nature no longer brings forth related phenomena in the ordering proper to them; 141 hence we are obliged to acquire the capacity of penetrating to this ordering by means of our own realistically trained observation and thought.

142 From among the various utterances of Goethe regarding his general conception of the ur-phenomenon, we here select a passage from that part of the historical section of his Theory of Colour 143 where he discusses the method of investigation introduced into science by Bacon. He says:

In the range of phenomena all had equal value in Bacon's eyes. 144 For although he himself always points out that one should collect the particulars only to select from them and to arrange them, in order finally to attain to Universals, yet too much privilege is granted to the single facts; 145 and before it becomes possible to attain to simplification and conclusion by means of induction-- the very way he recommends,-- life vanishes and forces get exhausted. 146 He who cannot realise that one instance is often worth a thousand, bearing all within itself; 147 he who proves unable to comprehend and esteem what we called ur-phenomena, will never be in a position to advance anything, either to his own or to others' joy and profit.'

148 What Goethe says here calls for the following comparison. We can say that Nature seen through Bacon's eyes appears as if painted on a two-dimensional surface, so that all its facts are seen alongside each other at exactly the same distance from the observer. 149 Goethe, on the other hand, ascribed to the human spirit the power of seeing the phenomenal world in all its three-dimensional multiplicity; 150 that is, of seeing it in perspective and distinguishing between foreground and background. 151 Things in the foreground he called ur-phenomena. Here the idea creatively determining the relevant field of facts comes to its purest expression. 152 The sole task of the investigator of Nature, he considered, was to seek for the ur-phenomena and to bring all other phenomena into relation with them; 153 and in the fulfilllment of this task he saw the means of fully satisfying the human mind's need to theorise. He expressed this in the words, 'Every fact is itself already theory'. 154 In Goethe's meteorological studies we have a lucid example of how he sought and found the relevant ur-phenomenon. It is the breathing-process of the earth as shown by the variations of barometric pressure.

155 Once again we find Thomas Reid, along his line of intuitively guided observation, coming quite close to Goethe where he deals with the question of the apprehension of natural law by the human mind. 156 He, too, was an opponent of the method of 'explaining' phenomena by means of abstract theories spun out of sheer thinking, and more than once in his writings he inveighs against it in his downright, humorous way. 157 His conviction that human thinking ought to remain within the realm of directly experienced observation is shown in the following words: 158 'In the solution of natural phenomena, all the length that the human faculties can carry us is only this, that from particular phenomena, we may, by induction, trace out general phenomena, of which all the particular ones are necessary consequences.' 159 As an example of this he takes gravity, leading the reader from one phenomenon to

the next without ever abandoning them, and concluding the journey by saying: 160 'The most general phenomena we can reach are what we call laws-of-Nature. So that the laws-of-Nature are nothing else but the most general facts relating to the operations of Nature, which include a great many particular facts under them.'

161 It was while on his way with the Grand Duke of Weimar to visit a newly erected meteorological observatory that Goethe, in the course of informing his companion of his own meteorological ideas, first heard of Howard's writings about the formation of clouds. 162 The Duke had read a report of them in a German scientific periodical, and it seemed to him that Howard's cloud system corresponded with what he now heard of Goethe's thoughts about the force relationships working in the different atmospheric levels. 163 He had made no mistake. Goethe, who immediately obtained Howard's essay, recognised at first glance in Howard's cloud scale the law of atmospheric changes which he himself had discovered. 164 He found here, what he had always missed in the customary practice of merely tabulating the results of scientific measurements. 165 And so he took hold of the Howard system with delight, for it 'provided him with a thread which had hitherto been lacking'.

166 Moreover, in the names which Howard had chosen for designating the basic cloud forms, Goethe saw the dynamic element in each of them coming to immediate expression in human speech. 167 He therefore always spoke of Howard's system as a 'welcome terminology'.

168 All this inspired Goethe to celebrate Howard's personality and his work in a number of verses in which he gave a description of these dynamic elements and a paraphrase of the names, moulding them together into an artistic unity. 169 In a few accompanying verses he honoured Howard as the first to 'distinguish and suitably name' the clouds.

170 The reason why Goethe laid so much stress on Howard's terminology was because he was very much aware of the power of names to help or hinder people in their quest for knowledge. 171 He

himself usually waited a long time before deciding on a name for a natural phenomenon or a connexion between phenomena which he had discovered. 172 The Idea which his spiritual eye had observed had first to appear so clearly before him that he could clothe it in a thought-form proper to it. 173 Seeing in the act of name-- giving an essential function of human (we are reminded of what in this respect the biblical story of creation says of Adam), Goethe called human 'the first conversation which Nature conducts with God'.

174 It is characteristic of Goethe that he did not content himself with knowing the truth which someone had brought forward in a field of knowledge in which he himself was interested, 175 but that he felt his acquaintance with this truth to be complete only when he also knew something about the personality of the man himself. 176 So he introduces his account of his endeavours to know more about Howard, the man, with the following words: 177 'Increasingly convinced that everything occurring through human should be regarded in an ethical sense, and that moral value is to be estimated only from a person's way of life, 178 I asked a friend in London to find out if possible something about Howard's life, if only the simplest facts.' 179 Goethe was uncertain whether the Englishman was still alive, so his delight and surprise were considerable when from Howard himself he received an answer in the form of a short autobiographical sketch, 180 which fully confirmed his expectations regarding Howard's ethical personality.

181 Howard's account of himself is known to us, as Goethe included a translation of it in the collection of his own meteorological studies. 182 Howard in a modest yet dignified way describes his Christian faith, his guide through all his relationships, whether to other people or to Nature. 183 A man comes before us who, untroubled by the prevailing philosophy of his day, was able to advance to the knowledge of an objective truth in Nature, because he had the ability to carry religious

experience even into his observation of the sense-world.

DYNAMICS VERSUS KINETICS

Ernst Lehrs

8 At the present time the human mind is in danger of confusing the realm of dynamic events, into which modern atomic research has penetrated, with the world of the spirit; 2 that is, the world whence Nature is endowed with intelligent design, and of which human thinking is an expression in terms of consciousness. 3 If a view of Nature as a manifestation of spirit, such as Goethe and kindred minds conceived it, is to be of any significance in our time, 4 it must include a conception of matter which shows as one of its attributes its capacity to serve Form-- in the sense in which Ruskin spoke of it in opposition to mere Force-- as a means of manifestation. 5 The present part of this book of matter, comprising Chapters 8 to11, will be devoted to working out such a conception of matter. 6 An example will thereby be given of how Goethe's method of acquiring understanding of natural phenomena through reading the phenomena themselves may be carried beyond his own field of observation. 7 There are, however, certain theoretical obstacles, erected by the onlooker-consciousness, which require to be removed before we can actually set foot on the new path. The present chapter will in particular serve this purpose.

8 Science, since Galileo, has been rooted in the conviction that the logic of mathematics is a means of expressing the behaviour of natural events. 9 The material for the mathematical treatment of sense data is obtained through measurement. The actual thing, therefore, in which the scientific observer is interested in each case, is the position of some kind of pointer. 10 In fact, physical science is essentially, as Professor Eddington put it, a 'pointer-reading science'. 11 Looking at this fact in our way we can say that all pointer instruments which human has constructed ever since the beginning of science, have as their model human, restricted to colourless, non-stereoscopic observation. 12 For all that is left

to him in this condition is to focus points in space and register changes of their positions. Indeed, the perfect scientific observer is himself the arch-pointer-instrument.

13 The birth of the method of pointer-reading is marked by Galileo's construction of the first thermometer (actually, a thermoscope). 14 The conviction of the applicability of mathematical concepts to the description of natural events is grounded in his discovery of the so-called Parallelogram of Forces. 15 It is with these two innovations that we shall concern ourselves in this chapter.

16 Let it be said at once that our investigations will lead to the unveiling of certain illusions which the spectator-consciousness has woven round these two gifts of Galileo. 17 This does not mean that their significance as fundamentals of science will be questioned. Nor will the practical uses to which they have been put with so much success be criticised in any way. But there are certain deceptive ideas which became connected with them, 18 and the result is that to-day, when human is in need of finding new epistemological ground under own feet, you are entangled in a network of conceptual illusions which prevent you from using your reason with the required freedom.

19 A special word is necessary at this point regarding the term illusion, as it is used here and elsewhere. 20 In respect of this, it will be well to remember what was pointed out earlier in connexion with the term 'tragedy' (Chapter-2). 21 In speaking of 'illusion', we neither intend to cast any blame on some person or another who took part in weaving the illusion, nor to suggest that the emergence of it should be thought of as an avoidable calamity. 22 Rather should illusion be thought of as something which human has been allowed to weave because only by your own active overcoming of it can you fulfilll your destiny as the bearer of truth in freedom. 23 Illusion, in the sense used here, belongs to those things in human's existence which are truly to be called tragic. 24 It loses this quality, and assumes a quite different one, only when human,

once the time has come for overcoming an illusion, insists on clinging to it.

25 As our further studies will show, the criticism to be applied here does not only leave the validity of measurement and the mathematical treatment of the data thus obtained fully intact, 26 but by giving them their appropriate place in a wider conception of Nature it opens the way to an ever more firmly grounded and, at the same time, enhanced application of both.

27 Our primary knowledge of the existence of something we call 'warmth' or 'heat' is due to a particular sense of warmth which modern research has recognised as a clearly definable sense. 28 Naturally, seen from the spectator-standpoint, the experiences of this sense appear to be of purely subjective value and therefore useless for obtaining an objective insight into the nature of warmth and its effects in the physical world. 29 In order to learn about these, resort is had to certain instruments which, through the change of the spatial position of a point, allow the onlooker-observer to register changes in the thermal condition of a physical object. An instrument of this kind is the thermometer. 30 In the following way an indubitable proof seems to be given of the correctness of the view concerning the subjectivity of the impressions obtained through the sense of warmth, and of the objectivity of thermometrical measurement. 31 A description of it is frequently given in physical textbooks as an introduction to the chapter on Heat.

32 To begin with, the well-known fact is cited that if one plunges one's hands first into two different bowls, one filled with hot water and the other with cold, and then plunges them together into a bowl of tepid water, 33 this will feel cold to the hand coming from the hot water and warm to the hand coming from the cold. 34 Next, it is pointed out that two thermometers which are put through the same procedure will register an equal degree of temperature for the tepid water. 35 In this way the student is given a lasting impression of the superiority of the 'objective'

recording of the instrument over the 'subjective' character of the experiences mediated by own sense of warmth.

36 Let us now test this procedure by carrying out the same experiment with the help of thermometrical instruments in their original form, that is, the form in which Galileo first applied them. 37 By doing so we proceed in a truly Goethean manner, because we divest the experiment of all accessories which prevent the phenomenon from appearing in its primary form.

38 To turn a modern thermometer into a thermoscope we need only remove the figures from its scale. 39 If we make the experiment with two such thermoscopes we at once become aware of something which usually escapes us, our attention being fixed on the figures recorded by the two instruments. 40 For we now notice that the two instruments, when transferred from the hot and cold water into the tepid water, behave quite differently. In one the column will fall, in the other it will rise.

41 It is important to note that by this treatment of the two instruments we have not changed the way in which they usually indicate temperature. 42 For thermometrical measurement is in actual fact never anything else than a recording of the movement of the indicator from one level to another. 43 We choose merely to take a certain temperature level-- that of melting ice or something else-- as a fixed point of reference and mark it once for all on the instrument. 44 Because we find this mark clearly distinguished on our thermometers, and the scales numbered accordingly, we fail to notice what lies ideally behind this use of the same zero for every new operation we undertake.

45 What the zero signifies becomes clear directly we start to work with thermometers not marked with scales. 46 For in order to be used in this form as real thermometers, they must be exposed on each occasion first of all to some zero level of temperature, say, that of melting ice. 47 If we then take them into the region of temperature we want to measure, we shall discern the difference of levels through the corresponding movement of the column. 48 The

final position of the column tells us nothing in itself. It is always the change from one level to another that the thermometer registers--precisely as does the sense of warmth in our hands in the experiment just described.

49 Hence we see that in the ordinary operation with the thermometers, and when we use our hands in the prescribed manner, we are dealing with the zero level in two quite different ways. 50 While in the two instruments the zero level is the same, in accordance with the whole idea of thermometric measurement, we make a special arrangement so as to expose our hands to two different levels. 51 So we need not be surprised if these two ways yield different results. If, after placing two thermometers without scales in hot and cold water, we were to assign to each its own zero in accordance with the respective height of its column, 52 and then graduate them from this reference point, they would necessarily record different levels when exposed to the tepid water, in just the same way as the hands do. 53 Our two hands, moreover, will receive the same sense-impression from the tepid water, if we keep them in it long enough.

54 Seen in this light, the original experiment, designed to show the subjective character of the impressions gained through the sense of warmth, reveals itself as a piece of self-deception by the onlooker-consciousness. 55 The truth of the matter is that, in so far as there is any subjective element in the experience and measurement of heat, it does not lie on the side of our sense of warmth, but in our judgment of the significance of thermometrical readings. 56 In fact, our test of the alleged proof of the absolute superiority of pointer-readings over the impressions gained by our senses gives us proof of the correctness of Goethe's statement, quoted earlier, 57 that the senses do not deceive, but the judgment deceives.

58 Let it be repeated here that what we have found in this way does not lead to any depreciation of the method of pointer-reading. For the direct findings of the senses cannot be compared quantitatively. 59 The point is that the idea of the

absolute superiority of physical measurement as a means of scientific knowledge, in all circumstances, must be abandoned as false.

60 We now turn to Galileo's discovery known as the theorem of the Parallelogram of Forces. The illusion which has been woven round this theorem expresses itself in the way it is described as being connected ideally with another theorem, 61 outwardly similar in character, known as the theorem of the Parallelogram of Movements (or Velocities), by stating that the former follows logically from the latter. 62 This statement is to be found in every textbook on physics at the outset of the chapter on dynamics (kinetics), 63 where it serves to establish the right to treat the dynamic occurrences in Nature in a purely kinematic fashion, true to the requirements of the onlooker-consciousness. 64 The following description will show that, directly we free ourselves from the onlooker-limitations of our consciousness in the way shown by Goethe-- and, in respect of the present problem, in particular also by Reid-- 65 the ideal relationship between the two theorems is seen to be precisely the opposite to the one expressed in the above statement. 66 The reason why we take pains to show this at the present point of our discussion is that only through replacing the fallacious conception by the correct one, do we open the way for forming a concrete concept of Force and thereby for establishing a truly dynamic conception of Nature.

67 Let us begin by describing briefly the content of the two theorems in question. In Fig. 1, a diagrammatical representation is given of the parallelogram of movements.

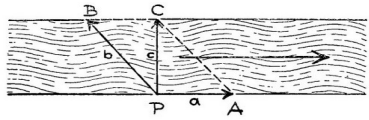

FIG. 1

68 It sets out to show that when a point moves with a certain velocity in the direction indicated by the arrow **a**, so that in a certain time it passes from **P** to **A**, 69 and when it simultaneously moves with a second velocity in the direction indicated by **b**, through which alone it would pass to **B** in the same time, its actual movement is indicated by **c**, the diagonal in the

parallelogram formed by **a** and **b**. 70 An example of the way in which this theorem is practically applied is the well-known case of a rower who sets out from **P** in order to cross at right angles a river indicated by the parallel lines. 71 He has to overcome the velocity **a** of the water of the river flowing to the right by steering obliquely left towards **B** in order to arrive finally at **C**.

72 It is essential to observe that the content of this theorem does not need the confirmation of any outer experience for its discovery, or to establish its truth. 73 Even though the recognition of the fact which it expresses may have first come to people through practical observation, yet the content of this theorem can be discovered and proved by purely logical means. 74 In this respect it resembles any purely geometrical statement such as, that the sum of the angles of a triangle is two right angles (180Â°). 75 Even though this too may have first been learn't through outer observation, yet it remains true that for the discovery of the fact expressed by it-- valid for all plane triangles-- no outer experience is needed. 76 In both cases we find ourselves in the domain of pure geometric conceptions (length and direction of straight lines, movement of a point along these), whose reciprocal relationships are ordered by the laws of pure geometric logic. 77 So in the theorem of the Parallelogram of Velocities we have a strictly geometrical theorem, whose content is in the narrowest sense kinematic. In fact, it is the basic theorem of kinematics.

78 We now turn to the second theorem which speaks of an outwardly similar relationship between forces. 79 As is well known, this states that two forces of different magnitude and direction, when they apply at the same point, act together in the manner of a single force 80 whose magnitude and direction may be represented by the diagonal of a parallelogram whose sides express in extent and direction the first two forces.

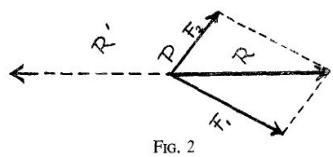

FIG. 2

81 Thus in Fig. 2, **R** exercises upon **P** the same effect as F1 and F2 together.

82 Expressed in another way, a force of this magnitude working in the reverse direction (R') will establish an equilibrium with the other two forces. 83 In technical practice, as is well known, this theorem is used for countless calculations, in both statics and dynamics, 84 and indeed more frequently not in the form given here but in the converse manner, when a single known force is resolved into two component forces. Distribution of a pressure along frameworks, of air pressure along moving surfaces, etc.

85 It will now be our task to examine the logical link which is believed to connect one theorem with the other. 86 This link is found in the well-known definition of physical force as a product of 'mass' and 'acceleration'-- in algebraic symbols F=ma. 87 We will discuss the implications of this definition in more detail later on. Let us first see how it is used as a foundation for the above assertion.

88 The conception of 'force' as the product of 'mass' and 'acceleration' is based on the fact-- easily experienced by anyone who cycles along a level road-- 89 that it is not velocity itself which requires the exertion of force, but the change of velocity-- that is, acceleration or retardation ('negative acceleration' in the sense of mathematical physics); 90 also that in the case of equal accelerations, the force depends upon the mass of the accelerated object. 91 The more massive the object, the greater will be the force necessary for accelerating it. 92 This mass, in turn, reveals itself in the resistance a particular object offers to any change of its state of motion. 93 Where different accelerations and the same mass are considered, the factor **m** in the above formula remains constant, and force and acceleration are directly proportional to each other. 94 Thus in the acceleration is discovered a measure for the magnitude of the force which thereby acts.

95 Now it is logically evident that the theorem of the parallelogram of velocities is equally valid for movements with constant or

variable velocities. 96 Even though it is somewhat more difficult to perceive mentally the movement of a point in two different directions with two differently accelerated motions, 97 and to form an inner conception of the resulting movement, we are nevertheless still within a domain which may be fully embraced by thought. 98 Thus accelerated movements and movements under constant velocity can be resolved and combined according to the law of the parallelogram of movements, a law which is fully attainable by means of logical thought.

99 With the help of the definition of force as the product of mass and acceleration it seems possible, indeed, to derive the parallelogram of forces from that of accelerations in a purely logical manner. 100 For it is necessary only to extend all sides of an a parallelogram by means of the same factor **m** in order to turn it into an **F** parallelogram. 101 A single geometrical figure on paper can represent both cases, since only the scale needs to be altered in order that the same geometrical length should represent at one time the magnitude **a** and on another occasion **ma**. 102 It is in this way that present-day scientific thought keeps itself convinced that the parallelogram of forces follows with logical evidence from the parallelogram of accelerations, and that the discovery of the former is therefore due to a purely mental process.

103 Since the parallelogram of forces is the prototype of each further mathematical representation of physical force-relationships in Nature, 104 the conceptual link thus forged between it and the basic theorem of kinematics has led to the conviction that the fact that natural events can be expressed in terms of mathematics could be, and actually has been, discovered through pure logical reasoning, 105 and thus by the brain-bound, day-waking consciousness 'of the world-spectator. 106 Justification thereby seemed to be given for the building of a valid scientific world-picture, purely kinematic in character.

107 The line of consideration we shall now have to enter upon for

carrying out our own examination of what is believed to be the link between the two theorems 108 may seem to the scientifically trained reader to be of an all too elementary kind compared with the complexities of thought in which he is used to engage in order to settle a scientific problem. 109 It is therefore necessary to state here that anyone who wishes to help to overcome the tangle of modern theoretical science must not be shy in applying thoughts and observations of seemingly so simple a nature as those used both here and on other occasions. 110 Some readiness, in fact, is required to play where necessary the part of the child in Hans Andersen's fairy-story of The Emperor's New Clothes, 111 where all the people are loud in praise of the magnificent robes of the Emperor, who is actually passing through the streets with no clothes on at all, and a single child's voice exclaims the truth that 'the Emperor has nothing on'. 112 There will repeatedly be occasion to adopt the role of this child in the course of our own studies.

113 In the scientific definition of force given above force appears as the result of a multiplication of two other magnitudes. 114 Now as is well known, it is essential for the operation of multiplication that of the two factors forming the product at least one should exhibit the properties of a pure number. 115 For two pure numbers may be multiplied together-- e.g. 2 and 4-- and a number of concrete things can be multiplied by a pure number-- e. g. 3 apples and the number 4-- 116 but no sense can be attached to the multiplication of 3 apples by 4 apples, let alone by 4 pears! 117 The result of multiplication is therefore always either itself a pure number, when both factors have this property; 118 or when one of the two factors is of the nature of a concrete object, the result is of the same quality as the latter. 119 An apple will always remain an apple after multiplication, and what distinguishes the final product (apples) from the original factor (apples) is only a pure number.

120 If we take seriously what this simple consideration tells us of the nature of multiplication, 121 and if

we do not allow ourselves to deviate from it for whatever purpose we make use of this algebraic operation, then the various concepts we connect with the basic measurements in physics undergo a considerable change of meaning.

122 Let us test, in this respect, the well-known formula which, in the conceptual language of physics, connects 'distance' (s), 'time' (t), and 'velocity' (c). It is written c = s / t, or s = ct.

123 In this formula, **s** has most definitely the meaning of **a** 'thing', for it represents measured spatial distance. 124 Of the two factors on the other side of the second equation, one must needs have the same quality as **s**: this is **c**. Thus for the other factor, **t**, there remains the property of a pure number. 125 We are, therefore, under an illusion if we assume the factor **c** to represent anything of what velocity implies in outer cosmic reality. 126 The truth is that **c** represents a spatial distance just as **s** does, with the difference only that it is a certain unit-distance. 127 Just as little does real time enter into this formula-- nor does it into any other formula of mathematical physics. 128 'Time', in physics, is always a pure number without any cosmic quality. Indeed, how could it be otherwise for a purely kinematic world-observation?

129 We now submit the formula **F=ma** to the same scrutiny. If we attach to the factor **a** on the right side of the equation a definite quality, namely an observable acceleration, the other factor in the product is permitted to have only the properties of a pure number; 130 **F**, therefore, can be only of the same nature as **a** and must itself be an acceleration. 131 Were it otherwise, then the equation F=ma could certainly not serve as a logical link between the Velocity and Force parallelograms.

132 Our present investigation has done no more than grant us an insight into the process of thought whereby the consciousness limited to a purely kinematic experience has deprived the concept of force of any real content. 133 Let us look at the equation F=ma as a means of splitting of the magnitude **F** into two components **m** and **a**. 134 The equation then tells us that **F** is reduced to the nature of pure

acceleration, for that which resides in the force as a factor not observable by kinematic vision has been split away from it as the factor **m**. 135 For this factor, however, as we have seen, nothing remains over but the property of a pure number. 136 Let us note here that the first thinker to concern himself with a comprehensive world-picture in which the non-existence of a real concept of force is taken in earnest-namely, Albert Einstein-- 137 was also the first to consider mass as a form of energy and even to predict correctly, as was proved later, the amount of energy represented by the unit of mass, 138 thereby encouraging decisively the new branch of experimental research which has led to the freeing of the so-called atomic energy. 139 Is it then possible that pure numbers can effect what took place above and within Nagasaki, Hiroshima, etc.? 140 Here we are standing once again before one of the paradoxes of modern science which we have found to play so considerable a part in its development.

141 To find an interpretation of the formula F=ma, which is free from illusion, we must turn our attention first of all to the concepts 'force' and 'mass' themselves. 142 The fact that people have these two words in their languages shows that the concepts expressed by them must be based on some experience that has been human's long before he was capable of any scientific reflexion. 143 Let us ask what kind of experience this is and by what part of his being he gathers it.

144 The answer is, as simple self-observation will show, that we know of the existence of force through the fact that we ourselves must exert it in order to move our own body. 145 Thus it is the resistance of our body against any alteration of its state of motion, as a result of its being composed of inert matter, which gives us the experience of force both as a possession of our own and as a property of the outer world. 146 All other references to force, in places where it cannot be immediately experienced, arise by way of analogy based on the similarity of the content of our observation to that which springs from the exertion of force in our own bodies.

MATTER

147 As we see, in this experience of force that of mass is at once implied. Still, we can strengthen the latter by experimenting with some outer physical object. 148 Take a fairly heavy object in your hand, stretch out your arm lightly and move it slowly up and down, watching intently the sensation this operation rouses in you. 149 Evidently the experience of mass outside ourselves, as with that of our own body, comes to us through the experience of the force which we ourselves must exert in order to overcome some resisting force occasioned by the mass. 150 Already this simple observation-- as such made by means of the sense of movement and therefore outside the frontiers of the onlooker-consciousness-- tells us that mass is nothing but a particular manifestation of force.

151 Seen in the light of this experience, the equation F=ma requires to be interpreted in a manner quite different from that to which scientific logic has submitted it. 152 For if we have to ascribe to **F** and **m** the same quality, then the rule of multiplication allows us to ascribe to a nothing but the character of a pure number. 153 This implies that there is no such thing as acceleration as a self-contained entity, merely attached to mass in an external way.

154 What we designate as acceleration, and measure as such, is nothing else than a numerical factor comparing two different conditions of force within the physical-material world. 155 Only when we give the three factors in our equation this meaning, does it express some concrete outer reality. 156 At the same time it forbids the use of this equation for a logical derivation of the parallelogram of forces from that of pure velocities.

157 The same method which has enabled us to restore its true meaning to the formula connecting mass and force will serve to find the true source of human's knowledge of the parallelogram of forces. Accordingly, our procedure will be as follows.

158 We shall engage two other persons, together with whom we shall try to discover by means of our respective experiences of force the law under which three forces

applying at a common point may hold themselves in equilibrium. 159 Our first step will consist in grasping each other by the hand and in applying various efforts of our wills to draw one another in different directions, 160 seeing to it that we do this in such a way that the three joined hands remain undisturbed at the same place. 161 By this means we can get as far as to establish that, when two persons maintain a steady direction and strength of pull, the third must alter own applied force with every change in own direction in order to hold the two others in equilibrium. 162 You will find that in some instances you must increase your pull and in other instances decrease it.

163 This, however, is all that can be learn't in this way. No possibility arises at this stage of our investigation of establishing any exact quantitative comparison. 164 For the forces which we have brought forth (and this is valid for forces in general, no matter of what kind they are) represent pure intensities, outwardly neither visible nor directly measurable. 165 We can certainly tell whether we are intensifying or diminishing the application of our will, but a numerical comparison between different exertions of will is not possible.

166 In order to make such a comparison, a further step is necessary. We must convey our effort to some pointer-instrument-- 167 for instance, a spiral spring which will respond to an exerted pressure or pull by a change in its spatial extension. (Principle of the spring balance.) 168 In this way, by making use of a certain property of matter-- elasticity-- the purely intensive magnitudes of the forces which we exert become extensively visible and can be presented geometrically. 169 We shall therefore continue our investigation with the aid of three spring balances, which we hook together at one end while exposing them to the three pulls at the other.

170 To mark the results of our repeated pulls of varying intensities and directions, we draw on the floor on which we stand three chalk lines outward from the point underneath the common point of the three instruments, 171 each in the direction taken up by

one of the three persons. Along these lines we mark the extensions corresponding to those of the springs of the instruments.

172 By way of this procedure we shall arrive at a sequence of figures such as is shown in Fig. 3. This is all we can discover empirically regarding the mutual relationships of three forces engaging at a point. 173 Let us now heed the fact that nothing in this group of figures reveals that in each one of these trios of lines there resides a definite and identical geometrical order; 174 nor do they convey anything that would turn our thoughts to the parallelogram of velocities with the effect of leading us to expect, by way of analogy, a similar order in these figures. 175 And this result, we note, is quite independent of our particular way of procedure, whether we use, right from the start, a measuring instrument, or whether we proceed as described above.

176 Having in this way removed the fallacious idea that the parallelogram of forces can, and therefore ever has been, conceived by way of logical derivation from the parallelogram of velocities, 177 we must then ask ourselves what it was, if not any act of logical reason, that led Galileo to discover it.

178 History relates that on making the discovery he exclaimed: 'La Natura Ã¨ scritta in lingua matematica!' ('Nature is recorded in the language of mathematics.') 179 These words reveal his surprise when he realised the implication of his discovery. Still, intuitively he must have known that using geometrical lengths to symbolise the measured magnitudes of forces would yield some valid result. 180 Whence came this intuition, as well as the other which led him to recognise from the figures thus obtained that in a parallelogram made up of any two of the three lines, the remaining line came in as its diagonal? 181 And, quite apart from the particular event of the discovery, how can we account for the very fact that Nature-- at least on a certain level of Her existence-- exhibits rules of action expressible in terms of logical principles immanent in the human mind?

MATTER

182 To find the answer to these questions we must revert to certain facts connected with human's psycho-physical make-up of which the considerations of Chapter -2 have already made us aware.

183 Let us, therefore, transpose ourselves once more into the condition of the child who is still entirely volition, and thus experiences the self as one with the world. 184 Let us consider, from the point of view of this condition, the process of lifting the body into the vertical position and the acquisition of the faculty of maintaining it in this position; 185 and let us ask what the soul, though with no consciousness of itself, experiences in all this. It is the child's will which wrestles in this act with the dynamic structure of external space, 186 and what the child’s will experiences is accompanied by corresponding perceptions through the sense of movement and other related bodily senses. 187 In this way the parallelogram of forces becomes an inner experience of our organism at the beginning of our earthly life. 188 What we thus carry in the body's will-region in the form of experienced geometry-- this, together with the freeing and crystallising of part of our will-substance into our conceptual capacity, 189 is transformed into our faculty of forming geometrical concepts, and among them the concept of the parallelogram of movements.

190 Looked at in this way, the true relationship between the two parallelogram-theorems is seen to be the very opposite of the one held with conviction by scientific thinking up to now. 191 Instead of the parallelogram of forces following from the parallelogram of movements, and the entire science of dynamics from that of kinematics, 192 our very faculty of thinking in kinematic concepts is the evolutionary product of our previously acquired intuitive experience of the dynamic order of the world.

193 If this is the truth concerning the origin of our knowledge of force and its behaviour on the one hand, and our capacity to conceive mathematical concepts in a purely ideal way on the other, 194 what is it then that causes human to dwell in such illusion as regards the

relationship between the two? 195 From our account it follows that no illusion of this kind could arise if we were able to remember throughout life our experiences in early childhood. 196 Now we know from our considerations in Chapter -6 that in former times human had such a memory. In those times, therefore, human was under no illusion as to the reality of force in the world. 197 In the working of outer forces human saw a manifestation of spiritual beings, just as in the self human experienced force as a manifestation of own spiritual being. 198 We have seen also that this form of memory had to fade away to enable human to find the self as a self-conscious personality between birth and death. 199 As such a personality, Galileo was able to think the parallelogram of forces, but he was unable to comprehend the origin of his faculty of mathematical thinking, 200 or of his intuitive knowledge of the mathematical behaviour of Nature in that realm of Hers where She sets physical forces into action.

201 Deep below in Galileo's soul there lived, as it does in every human being, the intuitive knowledge, acquired in early childhood, that part of Nature's order is recordable in the conceptual language of mathematics. 202 In order that this intuition should rise sufficiently far into his conscious mind to guide him, as it did, in his observations, 203 the veil of oblivion which otherwise separates our waking consciousness from the experiences of earliest childhood must have been momentarily lightened. 204 Unaware of all this, Galileo was duly surprised when in the onlooker-part of his being the truth of his intuition was confirmed in a way accessible to it, namely through outer experiment. 205 Yet with the veil immediately darkening again the onlooker soon became subject to the illusion that for his recognition of mathematics as a means of describing Nature he was in need of nothing but what was accessible to him on the near side of the veil.

206 Thus it became human's fate in the first phase of science, which

fills the period from Galileo and his contemporaries up to the present time, 207 that the very faculty which human needed for creating this science prevented him from recognising its true foundations. 208 Restricted as he was to the building of a purely kinematic world-picture, he had to persuade himself that the order of interdependence of the two parallelogram-theorems was the opposite of the one which it really is.

209 The result of the considerations of this chapter is of twofold significance for our further studies. 210 On the one hand, we have seen that there is a way out of the impasse into which modern scientific theory has got itself as a result of the lack of a justifiable concept of force, 211 and that this way is the one shown by Reid and travelled by Goethe. 'We must become as little children again, if we will be philosophers', is as true for science as it is for philosophy. 212 On the other hand, our investigation of the event which led Galileo to the discovery that Nature is recorded in the language of mathematics, has shown us that this discovery would not have been possible unless Galileo had in a sense become, albeit unconsciously, a little child again. 213 Thus the event that gave science its first foundations is an occurrence in human of precisely the same character as the one which we have learn't to regard as necessary for building science's new foundations. 214 The only difference is that we are trying to turn into a deliberate and consciously handled method something which once in the past happened to a human without one noticing it.

215 Need we wonder that we are challenged to do so in our day, when humankind is several centuries older than it was in the time of Galileo?

216 For the sake of our later studies it is essential that the reader does not content the self with merely following the above description mentally, but that you carries out the experiment yourself.

PRO LEVITATE

Ernst Lehrs

(I) ALERTNESS contra INERTNESS

MATTER

9 In the preceding chapter we gained a new insight into the relationship between mass and force. 2 We have come to see that our concept of force is grounded on empirical observation in no less a degree than is usually assumed for our concept of number, or size, or position, 3 provided we do not confine ourselves to non-stereoscopic, colourless vision for the forming of our scientific world-picture, but allow other senses to contribute to it. 4 As to the concept mass, our discussion of the formula F=ma showed that force and mass, as they occur in it, are of identical nature, both having the quality of force. 5 The factors *F* and *m* signify force in a different relationship to space (represented by the factor **a**). This latter fact now requires some further elucidation.

6 In a science based on the Goethean method of contemplating the world of the senses, concepts such as 'mass in rest' and 'mass in motion' lack any scientific meaning (though for another reason than in the theory of Relativity). 7 For in a science of this kind the universe-- in the sense propounded lately by Professor Whitehead and others-- appears as one integrated whole, whose parts must never be considered as independent entities unrelated to the whole. 8 Seen thus, there is no mass in the universe of which one could say with truth that it is ever in a state of rest. 9 Nor is there any condition of movement which could be rightly characterised by the attributes 'uniform' and 'straight line' in the sense of Newton's first law. 10 This does not mean that such conditions never occur in our field of observation. But as such they have significance only in relation to our immediate surroundings as a system of reference. 11 Even within such limits these conditions are not of a kind that would allow us to consider them as the basis of a scientific world-picture. 12 For as such they occur naturally only as ultimate, never as primeval conditions. 13 All masses are originally in a state of curvilinear movement whose rates change continuously. 14 To picture a mass as being in a state of rest, or of uniform motion in a straight line,

as the result of no force acting on it, 15 and to picture it undergoing a change in the rate and direction of its motion as the result of some outer force working on it, is a sheer abstraction. 16 In so far as mass appears in our field of observation as being in relative rest or motion of the kind described, this is always the effect of some secondary dynamic cause. 17 If we wish to think with the course of the universe and not against it, we must not start our considerations with the state of (relative) rest or uniform motion in a straight line 18 and derive our definition of force from the assumption that there is a primary 'force-free' state which is altered under the action of some force, 19 but we must arrange our definitions in such a way that they end up with this state. 20 Thus Newton's first law, for instance, would have to be restated somewhat as follows: No physical body is ever in a state of rest or uniform motion in a straight line, unless its natural condition is interfered with bythe particular action of some force.

21 Seen dynamically, and from the aspect of the universe as an interrelated whole, all aggregations of mass are the manifestation of certain dynamic conditions within the universe, 22 and what appears to us as a change of the state of motion of such a mass is nothing but a change in the dynamic relationship between this particular aggregation and the rest of the world. 23 Let us now see what causes of such a change occur within the field of our observation.

24 In modern textbooks the nature of the cause of physical movement is usually defined as follows: 'Any change in the state of movement of a portion of matter is the result of the action on it of another portion of matter.' 25 This represents a truth if it is taken to describe a certain kind of causation. 26 In the axiomatic form in which it is given it is a fallacy. 27 The kind of causation it describes is, indeed, the only one which has been taken into consideration by the scientific mind of human. 28 We are wont to call it 'mechanical' causation. Obviously, human's onlooker-consciousness is unable to

conceive of any other kind of causation. 29 For this consciousness is by its very nature confined to the contemplation of spatially apparent entities which for this reason can be considered only as existing spatially side by side. 30 For the one-eyed, colour-blind spectator, therefore, any change in the state of movement of a spatially confined entity could be attributed only to the action of another such entity outside itself. 31 Such a world-outlook was bound to be a mechanistic one.

32 We cannot rest content with this state of affairs if we are sincerely searching for an understanding of how spirit moves, forms, and transforms matter. 33 We must learn to admit non-mechanical causes of physical effects, where such causes actually present themselves to our observation. 34 In this respect our own body is again a particularly instructive object of study. For here mechanical and non-mechanical causation can be seen working side by side in closest conjunction. 35 Let us therefore ask what happens when we move, say, one of our limbs or a part of it.

36 The movement of any part of our body is always effected in some way by the movement of the corresponding part of the skeleton. 37 This in turn is set in motion by certain lengthenings and contractions of the appropriate part of the muscular system. 38 Now the way in which the muscles cause the bones to move falls clearly under the category of mechanical causation. 39 Certain portions of matter are caused to move by the movement of adjacent portions of matter. 40 The picture changes when we look for the cause to which the muscles owe their movements. 41 For the motion of the muscles is not the effect of any cause external to them, but is effected by the purely spiritual energy of our volition working directly into the physical substance of the muscles. 42 What scientific measuring instruments have been able to register in the form of physical, chemical, electrical, etc., changes of the muscular substance is itself an effect of this interaction. 43 To mark the fact that this type of causation is clearly distinguished from the type called mechanical, it

will be well to give it a name of its own. If we look for a suitable term, the word 'magical' suggests itself. 44 The fact that this word has gathered all sorts of doubtful associations must not hinder us from adopting it into the terminology of a science which aspires to understand the working of the super-sensible in the world of the senses. 45 The falling into disrepute of this word is characteristic of the onlooker-age. 46 The way in which we suggest it should be used is in accord with its true and original meaning, the syllable 'mag' signifying power or might (Sanskrit maha, Greek megas, Latin magnus, English might, much, also master). 47 Henceforth we shall distinguish between 'mechanical' and 'magical' causation, the latter being a characteristic of the majority of happenings in the human, animal and plant organisms.

48 Our next step in building up a truly dynamic picture of matter must be to try to obtain a direct experience of the condition of matter when it is under the sway of magical causation.

49 Let us first remember what is the outstanding attribute with which matter responds to mechanical causation. This is known to be inertia. 50 By this term we designate the tendency of physical matter to resist any outwardly impressed change of its existing state of movement. This property is closely linked up with another one, weight. 51 The coincidence of the two has of late become a puzzle to science, and it was Albert Einstein who tried to solve it by establishing his General Theory of Relativity. 52 The need to seek such solutions falls away in a science which extends scientific understanding to conditions of matter in which weight and inertia are no longer dominant characteristics. 53 What becomes of inertia when matter is subject to magical causation can be brought to our immediate experience in the following way. 54 The reader, even if you are already familiar with this experiment, is again asked to carry it out for yourself.

55 Take a position close to a smooth wall, so that one arm and hand, which are left hanging down

alongside the body, are pressed over their entire length between body and wall. 56 Try now to move the arm upward, pressing it against the wall as if you wanted to shift the latter. 57 Apply all possible effort to this attempt, and maintain the effort for about one minute. 58 Then step away quickly from the wall by more than the length of the arm, while keeping the arm hanging down by the side of the body in a state of complete relaxation. 59 Provided all conditions are properly fulfillled, the arm will be found rising by itself in accordance with the aim of the earlier effort, until it reaches the horizontal. 60 If the arm is then lowered again and left to itself, it will at once rise again, though not quite so high as before. 61 This can be repeated several times until the last vestige of the automatic movement has faded away.

62 Having thus ascertained by direct experience that there is a state of matter in which inertia is, to say the least, greatly diminished, 63 we find ourselves in need of giving this state-- which is present throughout Nature wherever material changes are brought into existence magically-- a name of its own, as we did with the two types of causation. 64 A word suggests itself which, apart from expressing adequately the peculiar self-mobility which we have just brought to our experience, goes well alongside the word 'inert' by forming a kind of rhyme with it. 65 This is the term 'alert'. With its help we shall henceforth distinguish between matter in the inert and alert conditions. 66 We shall call the latter state 'alertness', and in order to have on the other side a word as similar as possible in outer form to alertness, we suggest replacing the usual term inertia by 'inertness'. 67 Thus we shall speak of matter as showing the attribute of 'inertness', when it is subject to mechanical causation, of 'alertness', when it is subject to magical causation.

68 Anyone who watches attentively the sensation produced by the rising arm in the above experiment will be duly impressed by the experience of the alertness prevailing in the arm as a result of the will's magical intervention.

69 In our endeavour to find a modern way of overcoming the

conception of matter developed and held by science in the age of the onlooker-consciousness, we shall be helped by noticing how this conception first arose historically. 70 Of momentous significance in this respect is the discovery of the gaseous state of matter by the Flemish physician and experimenter, Joh. Baptist van Helmont (1577-1644). 71 The fact that the existence of this state of ponderable matter was quite unknown up to such a relatively recent date has been completely forgotten to-day. 72 Moreover, it is so remote from current notions that anyone who now calls attention to van Helmont's discovery is quite likely to be met with incredulity. 73 As a result, there is no account of the event that puts it in its true setting. 74 In what follows pains are taken to present the facts in the form in which one comes to know them through van Helmont's own account, given in his *Ortus Medicinae*.

75 For reasons which need not be described here, van Helmont studied with particular interest the various modifications in which carbon is capable of occurring in Nature-- among them carbon's combustion product, carbon dioxide. 76 It was his observations of carbon dioxide which made him aware of a condition of matter whose properties caused him the greatest surprise. 77 For he found it to be, at the same time, 'much finer than vapour and much denser than air'. 78 It appeared to him as a complete 'paradox', because it seemed to unite in itself two contradictory qualities, one appertaining to the realm of 'uncreated things', the other to the realm of 'created things'. 79 Unable to rank it with either 'vapour' or 'air'-- we shall see presently what these terms meant in van Helmont's terminology--, 80 he found himself in need of a special word to distinguish this new state from the other known states, both below and above it. 81 Since he could not expect any existing language to possess a suitable word, he felt he must create one. 82 He therefore took, and changed slightly, a word signifying a particular cosmic condition which seemed to be imaged in the new condition he had just discovered.

MATTER

83 The word was CHAOS. By shortening it a little, he derived from it the new word GAS. 84 His own words explaining his choice are: 'Halitum ilium GAS vocavi non longe a Chaos veterum secretum.'-- 'I have called this mist Gas, owing to its resemblance to the Chaos of the ancients.' 85 Van Helmont's account brings us face to face with a number of riddles. Certainly, there is nothing strange to us in his describing carbon dioxide gas as being 'finer than vapour and denser than air'; but why did he call this a 'paradox'? 86 What prevented him from ranking it side by side with air? As to air itself, why should he describe it as belonging to the realm of the 'uncreated things'? 87 What reason was there for giving 'vapour' the rank of a particular condition of matter? 88 And last but not least, what was the ancient conception of Chaos which led van Helmont to choose this name as an archetype for the new word he needed?

89 To appreciate van Helmont's astonishment and his further procedure, we must first call to mind the meaning which, in accordance with the prevailing tradition, he attached to the term Air. 90 For van Helmont, Air was one of the four 'Elements', EARTH, WATER, AIR, and FIRE. Of these, the first two were held to constitute the realm of the 'created things', the other two that of the 'uncreated things'. 91 A brief study of the old doctrine of the Four Elements is necessary at this point in order to understand the meaning of these concepts.

92 The first systematic teaching about the four elementary constituents of Nature, as they were experienced by human of old, was given by Empedocles in the fifth century B.C. It was elaborated by Aristotle. 93 In this form it was handed down and served to guide natural observation through more than a thousand years up to the time of van Helmont. 94 From our earlier descriptions of the changes in human's consciousness it is clear that the four terms, 'earth', 'water', 'air', 'fire', must have meant something different in former times. 95 So 'water' did not signify merely the physical substance which modern chemistry defines

by the formula H2O; nor was 'air' the mixture of gases characteristic of the earth's atmosphere. 96 Human in those days, on account of own particular relationship with Nature, was impressed in the first place by the various dynamic conditions, four in number, which one found prevailing both in own natural surroundings and in own organism. 97 With own elementary concepts one tried to express, therefore, the four basic conditions which one thus experienced. One saw physical substances as being carried up and down between these conditions.

98 At first sight some relationship seems to exist between the concept 'element' in this older sense and the modern view of the different states of material aggregation, solid, liquid, aeriform. 99 There is, however, nothing in this modern view that would correspond to the element Fire. 100 For heat in the sense of physical science is an immaterial energy which creates certain conditions in the three material states, 101 but from these three to heat there is no transition corresponding to the transitions between themselves. 100 Heat, therefore, does not rank as a fourth condition by the side of the solid, liquid and aeriform states, in the way that Fire ranks in the older conception by the side of Earth, Water and Air.

101 If we were to use the old terms for designating the three states of aggregation plus heat, as we know them to-day, we should say that there is a border-line dividing Fire from the three lower elements. 102 Such a border-line existed in the older conception of the elements as well. Only its position was seen to be elsewhere-- between Earth and Water on the one hand, Air and Fire on the other. 103 This was expressed by saying that the elements below this line constituted the realm of the 'created things', those above it that of the 'uncreated things'. 104 Another way of expressing this was by characterising Earth and Water with the quality Cold; Air and Fire with the quality Warm. The two pairs of elements were thus seen as polar opposites of one another.

105 The terms 'cold' and 'warm' must also be understood to have expressed certain qualitative

experiences in which there was no distinction as yet between what is purely physical and what is purely spiritual. 106 Expressions such as 'a cold heart', 'a warm heart', to 'show someone the cold shoulder', etc., still witness to this way of experiencing the two polar qualities, cold and warm. 107 Quite generally we can say that, wherever human experienced some process of contraction, whether physical or non-physical, you designated it by the term 'cold', and where you experienced expansion, you called it 'warm'. 108 In this sense you felt contractedness to be the predominant characteristic of Earth and Water, expansiveness that of Air and Fire.

109 With the help of these qualitative concepts we are now in a position to determine more clearly still the difference between the older and the modern conceptions: 110 in particular the difference between the aeriform condition of matter, as we conceive of it to-day, and the element Air. 111 Contractedness manifests as material density, or the specific weight of a particular substance. We know that this characteristic of matter diminishes gradually with its transition from the solid to the liquid and aeriform states. 112 We know also that this last state is characterised by a high degree of expansiveness, which is also the outstanding property of heat. 113 Thus there is reason to describe also from the modern point of view the solid and liquid states as essentially 'cold', and the aeriform state as 'warm'. 114 But aeriform matter still has density and weight, and this means that matter in this state combines the two opposing qualities. 115 Contrary to this, Air, as the second highest element in the old sense, is characterised by the pure quality, warm. 116 Thus, when human of old spoke of 'air', they had in mind something entirely free from material density and weight.

117 By comparing in this way the older and newer conceptions of 'air', we come to realise that ancient human must have had a conception of gravity essentially different from ours. 118 If we take gravity in the modern scientist's sense, as a 'descriptive law of behaviour', then this behaviour is

designated in the older doctrine by the quality 'cold'. 119 If, however, we look within the system of modern science for a law of behaviour that would correspond to the quality 'warm', we do so in vain. 120 Polarity concepts are certainly not foreign to the scientific mind, as the physics of electricity and magnetism show. Yet there is no opposite pole to gravity, as there is negative opposite to positive electricity, etc. 121 In the older conception, however, the gravitational behaviour 'cold' was seen to be counteracted by an autonomous anti-gravitational behaviour 'warm'. 122 Experience still supported the conviction that as a polar opposite to the world subject to gravity, there was another world subject to levity.

123 We refrain at this point from discussing how far a science which aspires to a spiritual understanding of Nature, including material processes, needs a revival-- in modern form-- of the old conception of levity. 124 In our present context it suffices to realise that we understand human's earlier view of Nature, and with it the one still held by van Helmont, only by admitting levity equally with gravity into his world-picture. 125 For the four elements, in particular, this meant that the two upper ones were regarded as representing Levity, the two lower ones Gravity. 126 In close connexion with this polar conception of the two pairs of elements, there stands their differentiation into one realm of created, another of uncreated, things. 127 To understand what these terms imply, we must turn to the ancient concept, Chaos, borrowed by van Helmont.

128 To-day we take the word Chaos to mean a condition of mere absence of order, mostly resulting from a destruction of existing forms, whether by nature or by the action of human. 129 In its original sense the word meant the exact opposite. When in ancient times people spoke of Chaos, they meant the womb of all being, the exalted realm of uncreated things, 130 where indeed forms such as are evident to the eye in the created world are not to be found, but in place of them are the archetypes of all visible forms, as though

nurtured in a spiritual seed-condition. 131 It is the state which in the biblical narration of the creation of the world is described as 'without form and void'. 132 From this Chaos all the four elements are born, one by one, with the two upper ones retaining Chaos's essential characteristic in that they are 'without form' and tend to be omnipresent, 133 whilst the two lower ones constitute a realm in which things appear in more or less clearly outlined space-bound forms. This is what the terms 'uncreated' and 'created' imply.

134 How strictly these two realms were distinguished can be seen by the occurrence of the concept 'vapour'. 135 When with the increasing interest in the realm of created things-- characteristic of the spectator-consciousness which, in view of our earlier description of it, we recognise as being itself a 'created thing'-- 136 the need arose for progressive differentiation within this realm, the simple division of it into 'earth' and 'water' was no longer felt to be satisfactory. 137 After all, above the liquid state of matter there was another state, less dense than water and yet presenting itself through more or less clearly distinguishable space-bound objects, 138 such as the mists arising from and spreading over ponds and meadows, and the clouds hovering in the sky. 139 For this state of matter the term 'vapour' had become customary, and it was used by van Helmont in this sense. 140 By its very properties, Vapour belonged to the realm of the created things, whereas Air did not. 141 It was the intermediary position of the newly discovered state of matter between Vapour and Air, that is, between the created and the uncreated world, which caused van Helmont to call it a paradox; 142 and it was its strange resemblance, despite its ponderable nature, to Chaos, which prompted him to name it-Gas.

143 Since it could not have been the gaseous state of matter in the form discovered by van Helmont, what particular condition of Nature was it to which the ancients pointed when using the term Air? 144 Let us see how the scriptures

of past human cultures speak of air.

In all older languages, the words used to designate the element bound up with breathing, 145 or the act of breathing, served at the same time to express the relationship of human to the Divine, or even the Divine itself. 146 One need think only of the words Brahma and Atma of the ancient Indians, the Pneuma of the Greeks, the Spiritus of the Romans. 147 The Hebrews expressed the same idea when they said that Jehovah had breathed the breath of life into human and that human in this way became a living soul. 148 What lies behind all these words is the feeling familiar to human in those times, that breathing was not only a means of keeping the body alive, but that a spiritual essence streamed in with the breath. 149 So long as this condition prevailed, people could expect that by changing their manner of breathing they had a means of bringing the soul into stronger relationship with spiritual Powers, as is attempted in Eastern Yoga.

150 Remembering the picture of human's spiritual-physical evolution which we have gained from earlier chapters, we are not astonished to find how different this early experience of the breathing process was from our own. 151 Yet, together with the recognition of this difference there arises another question. Even if we admit that human of old was so organised that the experience of own breathing process was an overwhelmingly spiritual one, 152 it was, after all, the gaseous substance of the earth's atmosphere which one inhaled, and exhaled again in a transformed condition. 153 What then was it that prevented humans-- apparently right up to the time of van Helmont-- from gaining the slightest inkling of the materiality of this substance? 154 To find an answer to this question, let us resort once more to our method of observing things genetically, combined with the principle of not considering parts without considering the whole to which they organically belong.

155 In modern science the earth is regarded as a mineral body

whereon the manifold forms of Nature appear as mere additions, arising more or less by chance; 156 one can very well imagine them absent without this having any essential influence on the earth's status in the universe. 157 The truth is quite different. For the earth, with everything that exists on it, forms a single whole, just as each separate organism is in its own way a whole. 158 This shows that we have no right to imagine the earth without humans, and to suppose that its cosmic conditions of being would then remain unaltered-- any more than we can imagine a human being deprived of some essential-organ and remaining human. 159 Humankind, and all the other kingdoms of Nature, are bound up organically with the earth from the start of its existence. 160 Moreover, just as the highest plants, seen with Goethe's eyes, are the spiritual originators of the whole realm of plants-- the creative Idea determining their evolution-- 161 so we see human, the highest product of earth evolution, standing behind this evolution as its Idea from the first, and determining its course. 162 The evolutionary changes which we observe in the earth and in human are in fact a single process, working through a variety of manifested forms.

163 From this conception of the parallel evolution of earth and human light falls also on the historic event represented by van Helmont's discovery. 164 Besides being a symptom of a revolution in human's way of experiencing the atmosphere, it speaks to us of some corresponding change in the spiritual-physical condition of the atmosphere itself. 165 It was then that people not only came to think differently about air, but inhaled and exhaled an air that actually was different. 166 To find out what kind of change this was, let us turn once more to human's own organism and see what it has to say concerning the condition under which matter is capable of being influenced by mechanical and magical causation respectively, in the sense already described. 167 What is it in the nature of the bones that makes them accessible to mechanical causation only, and what is it in the muscles that

allows our will to rouse them magically? 168 Bones and muscles stand in a definite genetic relationship to each other, the bones being, in relation to the muscles, a late product of organic development. 169 This holds good equally for everything which in the body of living nature takes the form of mineralised deposits or coverings. 170 Every kind of organism consists in its early stages entirely of living substance; in the course of time a part of the organism separates off" and passes over into a more or less mineralised condition. 171 Seen in this light, the distinction between bones and muscles is that the bones have evolved out of a condition in which the muscles persist, though to a gradually waning degree, throughout the life-time of the body. 172 The substance of the muscles, remaining more or less 'young', stands at the opposite pole from the 'aged' substance of the bones. 173 Hence it depends on the 'age' of a piece of matter whether it responds to magical or mechanical causation.

174 Let us state here at once, that this temporal distinction has an essential bearing on our understanding of evolutionary processes in general. 175 For if mineral matter is a late product of evolution-- and nothing in Nature indicates the contrary-- then to explain the origins of the world (as scientific theories have always done) 176 with the aid of events similar in character to those which now occur in the mineral realm, means explaining them against Nature's own evidence. 177 To find pictures of past conditions of the earth in present-day Nature, we must look in the regions where matter, because it is still 'youthful', is played through by the magical working of purposefully active spiritual forces. 178 Thus, instead of seeing in them the chance results of blind volcanic and similar forces, we must recognise in the formation and layout of land and sea an outcome of events more closely resembling those which occur during the embryonic development of a living organism. 179 What, then, does van Helmont's discovery of the gaseous state of matter tell us, if

we regard it in the light of our newly acquired insight into the trend of evolution both within and without human? 180 When, in the course of its growing older, humankind had reached the stage which is expressed by the emergence of the spectator-consciousness-consciousness, 181 that is, based on a nervous system which has grown more or less independent of the life forces of the organism-- 182 the outer elements had, in their way, arrived at such a state that human began to inhale an air whose spiritual-physical constitution corresponded exactly to that of own nervous system: 183 on either side, Spirit and Matter, in accordance with the necessities of cosmic evolution had lost their primeval union.

184 Our extension of the concept of evolution to the very elements of Nature, whether these are of material or non-material kind, and our recognition of this evolution as leading in general from a more alert to a more inert condition, 185 at once open the possibility of including in our scientific world-picture certain facts which have hitherto resisted any inclusion. 186 We mean those manifold events of 'miraculous' nature, of which the scriptures and the oral traditions of old are full. What is modern man to make of them?

187 The doubts which have arisen concerning events of this kind have their roots on the one hand in the apparent absence of such occurrences in our day, 188 on the other in the fact that the laws-of-Nature derived by science from the present condition of the world seem to rule them out.

189 In the light of the concept of the world's 'ageing' which we have tried to develop here, not only do the relevant reports become plausible, but it also becomes understandable why, if such events have taken place in the past, they fail to do so in our own time. 190 To illustrate this, let us take a few instances which are symptomatic of the higher degree of youthfulness which was characteristic in former times in particular of the element of Fire.

191 The role which Fire was capable of playing in human's life at a time when even this element, in itself the most youthful of all, was more susceptible to magic

interference than of late, is shown by the manifold fire-rites of old. 192 In those days, when no easy means of fire-lighting were available, it was usual for the needs of daily life to keen a fire burning all the time and to kindle other fires from it. 193 Only in cases of necessity was a new fire lit, and then the only way was by the tedious rubbing together of two pieces of dry wood.

194 Then both the maintenance of fires, and the deliberate kindling of a new fire, played quite a special role in the ceremonial ordering of human society. 195 Historically, much the best known is the Roman usage in the Temple of Vesta. On the one hand, the unintentional extinction of the fire was regarded as a national calamity and as the gravest possible transgression on the part of the consecrated priestess charged with maintaining the fire. 196 On the other hand, it was thought essential for this 'everlasting' fire to be newly kindled once a year. This took place with a special ritual at the beginning of the Roman year (1st March).

197 The conception behind such a ritual of fire-kindling will become clear if we compare with it certain other fire-rites which were practised in the northern parts of Europe, especially in the British Isles, until far on in the Christian era. 198 For example, if sickness broke out among the cattle, a widespread practice was to extinguish all the hearth-fires in the district and then to kindle with certain rites a new fire, from which all the local people lit their own fires once more. 199 Heavy penalties were prescribed for anyone who failed to extinguish own fire-- a failure usually indicated by the non-manifestation of the expected healing influence. 200 In Anglo-Saxon speaking countries, fires of this kind were known as 'needfires'.

The spiritual significance of these fires cannot be expressed better than by the meaning of the very term 'needfire'. 201 This word does not derive, as was formerly believed, from the word 'need', meaning a 'fire kindled in a state of need', but, as recent etymological research has shown, from a root which appears in the

German word nieten-- to clinch or rivet. 202 'Needfire' therefore means nothing less than a fire which was kindled for 'clinching' anew the bond between earthly life and the primal spiritual order at times when for one reason or another there was a call for this. 203 This explanation of the 'needfire' throws light also on the Roman custom of re-kindling annually the sacred fire in the Temple of Vesta. 204 For the Romans this was a means of reaffirming year by year the connexion of the nation with its spiritual leadership; 205 accordingly, they chose the time when the sun in its yearly course restores-- 're-clinches'-- the union of the world-spirit with earthly Nature, 206 for the rebirth of the fire which throughout the rest of the year was carefully guarded against extinction. 207 Just as people saw in this fire-kindling a way of bringing humanity into active relation with spiritual powers, so on the other hand were these powers held to use the fire element in outer Nature for the purpose of making themselves actively known to humankind. 208 Hence we find in the records of all ancient peoples a unanimous recognition of lightning and thunder on the one hand, and volcanic phenomena on the other, as means to which the Deity resorts for intervening in human destiny. 209 A well-known example is the account in the Bible of the meeting of Moses with God on Mount Sinai. 210 As occurrence in the early history of the Hebrews it gives evidence that even in historical times the fire element of the earth was sufficiently 'young' to serve the higher spiritual powers as an instrument for the direct expression of their will.

(II) LEVITY contra GRAVITY

211 We said earlier in this chapter that a science which aspires to a spiritual understanding of the physical happenings in Nature must give up the idea that inertness and weight are absolute properties of matter. 212 We were able at once to tackle the question of inertness by bringing to our immediate observation matter in the state of diminished inertness, or, as we proposed to say, of

alertness. 213 We are now in a position to go into the other question, that of weight or gravity. Just as we found inertness to have its counterpart in alertness, both being existing conditions of matter, 214 so we shall now find in addition to the force of gravity another force which is the exact opposite of it, and to which therefore we can give no better name than 'levity'.

215 Already, indeed, the picture of Nature which we gained from following Goethe's studies both of the plant and of meteorological happenings has brought us face to face with certain aspects of levity. 216 For when Goethe speaks of systole and diastole, as the plant first taught him to see them and as later he found them forming the basic factors of weather-formation, he is really speaking of the ancient concepts, 'cold' and 'warm'. 217 Goethe's way of observing Nature is, in fact, a first step beyond the limits of a science which kept itself ignorant of levity as a cosmic counterpart to terrestrial gravity. 218 To recognise the historical significance of this step, let us turn our glance to the moment when the human mind became aware that to lay a proper foundation for the science it was about to build, it had to exclude any idea of levity as something with a real existence. 219 Many a conception which is taken for granted by modern human, and is therefore assumed to have been always obvious, was in fact established quite deliberately at a definite historical moment. 220 We have seen how this applies to our knowledge of the gaseous state of matter; it applies also to the idea of the uniqueness of gravity. 221 About half a century after van Helmont's discovery a treatise called Contra Levitatem was published in Florence by the Accademia del Cimento. 222 It declares that a science firmly based on observation has no right to speak of Levity as something claiming equal rank with, and opposite to, Gravity.

223 This attitude was in accord with the state into which human consciousness had entered at that time. 224 For a consciousness which is itself of the quality 'cold', because it is based on the contracting forces of the body, is

naturally not in a position to take into consideration its very opposite. 225 Therefore, to speak of a force of levity as one felt able to speak of gravity was indeed without meaning.

226 Just as there was historical necessity in this banishing of levity from science at the beginning of the age of the spectator-consciousness, 227 so was there historical necessity in a renewed awareness of it arising when the time came for human to overcome the limitations of own spectator-relationship to the world. 228 We find this in Goethe's impulse to search for the action of polarities in Nature. As we shall see later, it comes to its clearest expression in Goethe's optical conceptions.

229 Another witness to this fact is Ruskin, through a remark which bears in more than one sense on our present subject. It occurs in his essay, The Storm-Cloud of the Ninteenth Century. 230 In its context it is meant to warn the reader against treating science, which Ruskin praises as a fact-finding instrument, as an interpreter of natural facts. 231 Ruskin takes Newton's conception of gravity as the all-moving cause of the universe, and turns against it in the following words:

232 'Take the very top and centre of scientific interpretation by the greatest of its masters: Newton explained to you-- or at least was once supposed to explain, why an apple fell; 233 but he never thought of explaining the exact correlative but infinitely more difficult question, how the apple got up there.'

234 This remark shows Ruskin once again as a true reader in Nature's book. 235 Looking with childlike openness and intensity of participation into the world of the senses, he allows Nature's phenomena to impress themselves upon his mind without giving any preconceived preference to one kind or another. 236 This enables him not to be led by the phenomenon of falling bodies to overlook the polarically opposite phenomenon of the upward movement of physical matter in the living plant. 237 Ruskin's remark points directly to the new world-conception which must be striven for to-day-- the conception

in which death is recognised as a secondary form of existence preceded by life; 238 in which levity is given its rightful place as a force polar to gravity; and in which, because life is bound up with levity as death is with gravity, levity is recognised as being of more ancient rank than gravity.

239 In proceeding now to a study of levity we shall not start, as might be expected, with plants or other living forms. 240 We are not yet equipped to understand the part played by levity in bringing about the processes of life; we shall come to this later. 241 For our present purpose we shall look at certain macrotelluric events-- events in which large areas of the earth are engaged-- taking our examples from meteorology on the one hand and from seismic (volcanic) processes on the other.

242 In pursuing this course we follow a method which belongs to the fundamentals of a Goetheanistic science. A few words about this method may not be out of place.

243 When we strive to read the book of Nature as a script of the spirit we find ourselves drawn repeatedly towards two realms of natural phenomena. 244 They are widely different in character, but studied together they render legible much that refuses to be deciphered in either realm alone. 245 These realms are, on the one hand, the inner being of human, and, on the other, the phenomena of macrotelluric and cosmic character. 246 The fruitfulness of linking together these two will become clear if we reflect on the following. The field of the inner life of human allows us, as nothing else does, to penetrate it with our own intuitive experience. 247 For we ourselves are always in some sense the cause of the events that take place there. 248 In order to make observations in this region, however, we need to bring about a certain awakening in a part of our being which-- so long as we rely on the purely natural forces of our body-- remains sunk in more or less profound unconsciousness.

249 If this realm of events is more intimately related than any other to our intuitive experience, it has also the characteristic of remaining closed to any research by external means. 250 Much of what lies

beyond the scope of external observation, however, reveals itself all the more clearly in the realms where Nature is active on the widest scale. 251 Certainly, we must school ourselves to read aright the phenomena which come to light in those realms. 252 And once more we must look to the way of introspection, previously mentioned, for aid in investing our gaze with the necessary intuitive force. 253 If we succeed in this, then the heavens will become for us a text wherein secrets of human nature, hidden from mere introspection, can be read; 254 while at the same time the introspective way enables us to experience things which we cannot uncover simply by observing the outer universe. 255 Apart from these methodological considerations, there is a further reason for our choice. Among the instances mentioned earlier in this chapter as symptoms of a greater 'youthfulness' prevailing in Nature, 256 and particularly in the element Fire, at a comparatively recent date, were the manifestations of the Divine-Spiritual World to human reported in the Bible as the event on Mount Sinai. 257 There, thunder and lightning from above and volcanic action from below form the setting for the intercourse of Jehovah with Moses. 258 To-day the function of these types of phenomena, though metamorphosed by the altered conditions of the earth, is not essentially different. 259 Here, more than in any other sphere of Her activities, Nature manifests that side of Her which we are seeking to penetrate with understanding.

260 Let us start with an observation known to the present writer from a visit to the Solfatara, a volcanic region near Naples. 261 The Solfatara itself is a trough surrounded by hilly mounds; its smooth, saucepan-like bottom, covered with whitish pumice-sand, is pitted with craters containing violently boiling and fuming mud -- the so-called fango, famous for its healing properties. 262 All around sulphurous fumes issue from crevices in the rocks, and in one special place the Solfatara reveals its subterranean activity by the emergence of fine, many-coloured sand, which oozes up like

boiling liquid from the depths below. 263 The whole region gives the impression of being in a state of labile balance. How true this is becomes apparent if one drops pieces of burning paper here and there on the ground: immediately a cloud of smoke and steam rises. 264 The effect is even more intense if a burning torch is moved about over one of the boiling fango holes. Then the deep answers instantly with an extraordinary intensification of the boiling process. 265 The hot mud seems to be thrown into violent turmoil, emitting thick clouds of steam, which soon entirely envelop the spectator near the edge.

266 The scientific mind is at first inclined to see in this phenomenon the mechanical effect of reduced air-pressure, due to the higher temperatures above the surface of the boiling mud, though doubts are raised by the unusual intensity of the reaction. 267 The feeling that the physical explanation is inadequate is strengthened when the vapours have thinned out and one is surprised to see that every crack and cranny in the Solfatara, right up to the top of the trough, shows signs of increased activity. 268 Certainly, this cannot be accounted for by a cause-and-effect nexus of the kind found in the realm of mechanical causation, where an effect is propagated from point to point and the total effect is the sum of a number of partial effects. 269 It looks rather as if the impulse applied in one spot had called for a major impulse which was now acting on the Solfatara as a whole.

270 As observers who are trying to understand natural phenomena by recognising their significance as letters in Nature's script, we must look now for other phenomena which can be joined with this one to form the relevant 'word' we have set out to decipher.

271 All scientific theories concerning the causes of seismic occurrences, both volcanic and tectonic, have been conceived as if the spatial motion of mineral matter were the only happening that had to be accounted for. 272 No wonder that none of these theories has proved really satisfactory even to mechanistically orientated thinking. 273 Actually there are

phenomena of a quite different kind connected with the earth's seismic activities, and these need to be taken into equal account. 274 There is, for instance, the fact that animals often show a premonition of volcanic or tectonic disturbances. They become restive and hide, or, if domestic, seek the protection of human. 275 Apparently, they react in this way to changes in Nature which precede the mechanical events by which human registers the seismic occurrence.

276 Another such phenomenon is the so-called earthquake-sky, which the present writer has had several occasions to witness. 277 It consists of a peculiar, almost terrifying, intense discoloration of the sky, and, to those acquainted with it, is a sure sign of an imminent or actual earthquake somewhere in the corresponding region of the earth. 278 This phenomenon teaches us that the change in the earth's condition which results in a violent movement of her crust, involves a region of her organism far greater than the subterranean layers where the cause of the purely mechanical events is usually believed to reside. 279 That human is not excluded from experiencing directly the super-spatial nature of seismic disturbances is shown by an event in Goethe's life, 280 reported by his secretary Eckermann, who himself learn't the story from an old man who had been Goethe's valet at the time.

281 This is what the old man, whom Eckermann met by accident one day near Weimar, told him: 'Once Goethe rang in the middle of the night and when I entered his room I found he had rolled his iron bed to the window and was lying there, gazing at the heavens. 282 "Have you seen nothing in the sky?" asked he, and when I answered "No", he begged me to run across to the sentry and inquire of the man on duty if he had seen nothing. 283 He had not noticed anything and when I returned I found the master still in the same position, gazing at the sky. 284 "Listen," he said, "this is an important moment; there is now an earthquake or one is just going to take place." Then he made me sit down on the bed and showed me by what signs he knew this.' 285

MATTER

When asked about the weather conditions, the old man said: 'It was very cloudy, very still and sultry.' 286 To believe implicitly in Goethe was for him a matter of course, 'for things always happened as he said they would'. 287 When next day Goethe related his observations at Court, the women tittered: 'Goethe dreams' ('Goethe schwÃ¤rmt'), but the Duke and the other men present believed him. 288 A few weeks later the news reached Weimar that on that night (5th April, 1783) part of Messina had been destroyed by an earthquake.

289 There is no record by Goethe himself of the nature of the phenomenon perceived by him during that night, except for a brief remark in a letter to Mme de Stein, written the following day, 290 in which he claims to have seen a 'northern light in the south-east' the extraordinary character of which made him fear that an earthquake had taken place somewhere. 291 The valet's report makes us inclined to think that there had been no outwardly perceptible phenomenon at all, 292 but that what Goethe believed he was seeing with his bodily eyes was the projection of a purely super-sensible, but not for that reason any less objective, experience.

293 In a picture of the seismic activities of the earth which is to comprise phenomena of this kind, the volcanic or tectonic effects cannot be attributed to purely local causes. 294 For why, then, should the whole meteorological sphere be involved, and why should living beings react in the way described? 295 Clearly, we must look for the origin of the total disturbance not in the interior of the earth but in the expanse of surrounding space. 296 Indeed, the very phenomenon of the Solfatara, if seen in this light, can reveal to us that at least the volcanic movements of the earth's crust are not caused by pressure from within, but by suction from without-- that is, by an exceptional action of levity.

297 We recall the fact that the whole Solfatara phenomenon had its origin in a flame being swayed over one of the fango holes. 298 Although it remains true that the suction arising from the

diminished air pressure over the hole cannot account for the intense increase of ebullition in the hole itself, 299 not to speak of the participation of the entire region in this increase, there is the fact that the whole event starts with a suctional effect. 300 As we shall see in the next chapter, any local production of heat interferes with the gravity conditions at that spot by shifting the balance to the side of levity. 301 That the response in a place like the Solfatara is what we have seen it to be, is the result of an extraordinary liability of the equilibrium between gravity and levity, a characteristic appertaining to the earth's volcanism in general.

302 For the people living near the Solfatara it is indeed common knowledge that there are times when this liability is so great that the slightest local disturbance of the kind we have described can provoke destructive eruptions of great masses of subterranean mud.-- At such times access to the Solfatara is prohibited. 303 We shall understand such an eruption rightly if we picture it as the counter-pole of an avalanche. 304 The latter may be brought about by a fragment of matter on a snow-covered mountain, perhaps a little stone, breaking loose and in its descent bringing ever-accumulating masses of snow down with it. 305 The levity-process polar to this demonstration of gravity is the production of a mightily growing 'negative avalanche' by comparatively weak local suction, caused by a small flame.

306 Earlier in this chapter we said that if we want to understand how spirit moves, forms and transforms matter, we must recognise the existence of non-mechanical (magical) causes of physical effects. 307 We have now found that the appearance of such effects in Nature is due to the operations of a particular force, levity, polar to gravity. 308 Observation of a number of natural happenings has helped us to become familiar in a preliminary way with the character of this force. 309 Although these happenings were all physical in appearance, they showed certain definitely non-physical features, particularly through their peculiar relationship to three-dimensional space. More characteristics of this

kind will appear in the following pages.

310 In this way it will become increasingly clear that in levity we have to do with something which, despite its manifesting characteristics of a 'force' not unlike gravity and thereby resembling the latter, differs essentially from anything purely physical. 311 It is only by its interactions with gravity that levity brings about events in the physical world-events, however, which are themselves partly of a physical, partly of a super-physical kind. 312 Seeing things in this aspect, we are naturally prompted to ask what causes there are in the world which make gravity and levity interact at all. 313 This question will find its answer in due course. First, we must make ourselves more fully acquainted with the various appearances of the gravity-levity interplay in Nature.

THE FOURTH STATE OF MATTER

Ernst Lehrs

10 When William Crookes chose as one of the titles of his paper on the newly discovered properties of electricity, '*The Fourth State of Matter*', it was to express his belief that he had found a state of matter, additional to the three known ones, 2 which represented 'the borderland where matter and force seem to merge into one another, the shadowy realm between known and unknown' for which his soul had been longing ever since the death of his beloved brother. 3 All that has followed from his discovery, down to the transformation of matter itself into freely working energy, shows that he was right in thinking he had reached some borderland of Nature. 4 But the character of the forces which are thus liberated makes it equally clear that this is not the borderland he was looking for. 5 Nature-- by which we mean physical Nature-- has in fact two borders, one touching the realm of the intramaterial energies which are liberated by disrupting the

structure of atomic nuclei, 6 the other leading over into creative Chaos, the fountain-head of all that appears in Nature as intelligent design. 7 It was Crookes's fate to open the road which has brought human to Nature's lower border and even across it, although he himself was in search of Her upper border. 8 What he was denied, we are in a position to achieve to-day, provided we do not expect to succeed by methods similar to those of atomic physics, and do not look for similar results.

9 To show that there is a fourth state of matter, rightly so called, which represents in actual fact the upper border of Nature, and to point the way that leads to it and across it, is the purpose of this chapter.

10 From our previous comparison of the older conception of the four elementary conditions of Nature with that now held of the three states of ponderable matter, we may expect that the fourth state will have something in common with heat. 11 Heat is indeed the energy which transforms matter by carrying it from the solid to the liquid and gaseous states. 12 Not so obvious is the fact that heat, apart from being an agent working at matter in this way, is the very essence underlying all material existence, out of which matter in its three ponderable states comes into being and into which it is capable of returning again. 13 Such a conception of matter was naturally absent from the age of the Contra-Levitatem orientation of the human mind. To create this conception, a new Pro-Levitate orientation is required.

14 Apart from producing liquefaction and vaporisation, heat has also the property of acting on physical matter so that its volume increases. Both facts are linked together by science through the thermodynamic conception of heat. 15 As this conception firmly blocks the road to the recognition of the role of heat as the fourth state of matter, our first task will be to determine our own standpoint with regard to it. 16 Further obstacles on our way are the so-called Laws of Conservation, which state that no matter and no energy-- which for present-day science have become

one and the same thing-- can ever disappear into 'nothing' or come into being out of 'nothing'. 17 This idea, also, will therefore require our early attention.

18 In the light of our previous studies we shall not find it difficult to test the reality-value of the thermodynamic conception of heat. 19 As we know of mass through a definite sense-perception, so we know of heat. In the latter case we rely on the sense of warmth. 20 In Chapter-8 we took the opportunity to test the objectivity of the information received through this sense. 21 Still, one-eyed, colour-blind observation is naturally unable to take account of these sense-messages. 22 To this kind of observation nothing is accessible, we know, except spatial displacements of single point-like entities. 23 Hence we find Bacon and Hooke already attributing the sensation of warmth to minute fast-moving particles of matter impinging on the skin. 24 Some time later we find Locke taking up the same picture. We see from this how little the mechanical theory of heat owes to empirical facts. 25 For even in Locke's time the connexion between heat and mechanical action, as recognised to-day, was completely unknown.

26 With this idea firmly rooted in his mind, modern human had no difficulty in using it to explain both thermal expansion and the effect of heat on the different states of matter, and so, finally, these states themselves. 27 Thermal expansion was thus attributed to an increase in the average distance between the assumed minute particles, caused by an increase in their rate of movement; 28 the liquid state was held to differ from the solid, and similarly the gaseous from the liquid, by the inter-spaces between the particles becoming relatively so great that the gravitational pull between them became too weak to hold them together.

29 Tested from a view-point outside the onlooker-consciousness, this whole picture of the interaction between matter and heat appears to run counter to the cosmic order of things in a way typical of other spectator-theories. 30 Ancient human, if confronted with this picture, would have said

that it means explaining the element Fire by the quality Cold. 31 For each of those minute particles, in its solidity and state of spatial separation from the others, represents an effigy of the earth and thereby the element Earth itself. 32 They would be unable to understand why phenomena of the 'warm' element Fire should be explained by its very opposite. 33 Moreover, Fire forms part of the ever 'youthful' realm of the world, whereas anything which exists as a spatially discernible entity, capable of being moved about mechanically, must have grown cosmically 'old'.

34 That Ruskin was as much on the alert in regard to this theory as he was in regard to Newton's theory of gravitation, is shown by the following utterance from his The Queen of the Air. 35 Obviously stirred by Tyndall's newly published treatise, Heat as a Mode of Motion, Ruskin felt the need to critise the endeavour of contemporary science 'to simplify the various forms of energy more and more into modes of one force, 36 or finally into mere motion, communicable in various states, but not destructible', by declaring that he would himself 'like better in order of thought to consider motion as a mode of heat than heat as a mode of motion'.

37 These words of Ruskin touch also on the law of conservation of energy, of which we said that it also called for a preliminary examination. What we now have to find out is the factual basis on which this law rests.

38 The conception of the law of conservation of energy arose from the discovery of the constant numerical relation between heat and mechanical work, known as the mechanical equivalent of heat. 39 This discovery was made at about the same time by Joule in England and J. R. Mayer in Germany, although by entirely different routes. 40 Joule, a brewer, was a man of practical bent. Trained by Dalton, the founder of the atomic theory, in experimental research, 41 he continued Rumford's and Davy's researches which they had undertaken to prove that heat is not, as it was for a time believed to be, a ponderable substance, but an imponderable

agent. 42 As a starting-point he took the heating effect of electric currents. 43 The fact that these could be generated by turning a machine, that is, by the expenditure of mechanical energy, gave him the idea of determining the amount of work done by the machine and then comparing this with the amount of heat generated by the current. 44 A number of ingenious experiments enabled him to determine with increasing exactitude the numerical relation between work and heat, as well as to establish the absolute constancy of the relation.

45 This he regarded as proof of the mechanical theory of heat, which he had taken from Rumford and Davy. 46 What simpler explanation could there be for the constant numerical relation between work and heat than the conception that transformation of one form of energy into another was simply a transmission of motion from one object to another? 47 From the quantitative equality of expended and generated energy was it not natural to argue the qualitative similarity of the two forms of energy, which only externally seemed different? 48 It was by quite a different path that the Heilbronn doctor, Mayer, arrived at his results. 49 To escape from the narrowness of his South German home town, he went, while still a youth, as doctor to a Dutch ship sailing to Java. 50 When in the tropics he treated a number of sailors by blood-letting, he observed that the venous blood was much nearer in colour to the paler arterial blood than was usual at home. 51 This change in the colour he attributed to the diminished intensity of bodily combustion, due, he believed, to the higher temperature of the tropics.

52 Scarcely had this thought passed through his mind than it induced another-- that of a universal interrelationship between all possible forms of energy. 53 This last idea so took possession of him that during the return voyage, as he himself related, he could scarcely think of anything but how to prove the correctness of his idea and what the consequences would be for the general view of Nature. 54 From the moment of his return he devoted his life to practical

research into the connexion between the various manifestations of energy. 55 It was in this way that he was led to the determination of the so-called mechanical equivalent of heat, shortly before the same discovery was made in a quite different manner by Joule.

56 If one considers how slender a connexion there was between Mayer's observation on the sailors in Java and the idea of the quantitative equilibrium of all physical nature-forces, 57 and if one contrasts this with the fanaticism he showed during the rest of his life in proving against all obstacles the correctness of his idea, 58 one must feel that the origin of the thought in Mayer's mind lay elsewhere than in mere physical observations and logical deductions. 59 Confirmation of this may be found in what Mayer himself declared to be his view concerning the actual grounds for the existence of a constant numerical association between the various manifestations of natural energy.

60 So far as science allowed Mayer any credit for his work, this was based on the opinion that through his discovery he had provided the final vindication of the mechanical theory of heat. 61 This judgment, however, was only piling one wrong upon another. 62 Mayer's destiny was truly tragic. When he began to publicise his conviction of the numerical equilibrium between spent and created energy, he met with so much scepticism, even derision, that from sheer despair his mind at times became clouded. 63 When at last toward the end of his life he received the recognition his discovery deserved-- not before being dragged through a painful priority dispute which Joule forced upon him and lost,-- 64 the scientists had begun to use his idea for bolstering up a hypothesis directly counter to the idea which had led him to his discovery, and for the sake of which he had accepted so much suffering.

65 Mayer's spiritual kin are not to be found among the heat-theorists of his time, such as Helmholtz and others, but among thinkers of the stamp of Goethe, Howard and Ruskin. 66 His basic idea of the inner connexion between all forms

of energy in Nature corresponds entirely with Goethe's idea of metamorphosis. 67 Just as Goethe saw in the ur-plant the Idea common to all plant-forms or, in the various plant-organs, the metamorphosis of one and the same ur-organ, 68 so was Mayer convinced of the existence of an ur-force which expressed itself in varying guises in the separate energy-forms of Nature. 69 In the picture of the physical universe which hovered before him, the transformation of one form of energy into another-- such as mechanical energy into electrical, this into chemical and so on-- 70 was somewhat similar to Goethe's picture of the organic life of the earth, in which the metamorphosis of one living form into another constantly occurred. 71 'There is in Nature', said Mayer, 'a specific dimension of immaterial constitution which preserves its value in all changes taking place among the objects observed, whereas its form of appearance alters in the most manifold ways.' 72 For the physicist, accustomed to a purely quantitative observation of Nature, it is difficult to comprehend that Mayer could have arrived at the thought of a constant quantitative relation between the various manifestations of natural energy, 73 without deriving from it the conviction of their qualitative identity-- i.e., without concluding from the existence of the mechanical heat--equivalent that heat is itself nothing else than a certain form of spatial movement. 74 Mayer actually had a picture directly contrary to the mechanistic conception. For him, the arising of heat represented a disappearance of mechanical energy.

75 If this, then, was Mayer's belief, what was it that convinced him of the existence of a numerical balance between appearing and vanishing energy, even before he had any experimental proof?

76 Later in this book there will be occasion to introduce a concept of number in tune with our qualitative world-outlook. 77 What led Mayer to look upon number as an expression of existing spiritual associations in Nature will then become clear. 78 Let this much be said here, that number in the universe has quite different

functions from that of serving merely as an expression for a total of calculable items, or as a means of comparing spatial distances. 79 It is in the nature of the onlooker-consciousness that it is unable to interpret numerical equality between natural phenomena save as indicating the presence of an equal number of calculable objects or of spatial movements of equal magnitude. 80 It was therefore consistent for such a consciousness to regard the discovery by Mayer of the mechanical heat-equivalent as a confirmation of the existing mechanical conception of heat.

81 For Mayer such an interpretation was not necessary. His conviction of the existence of an ur-force, manifesting through metamorphosis in all natural forces, led him to expect a constant numerical relation amongst these, 82 without requiring him to deny the objective existence of qualitative differences, as these displayed themselves in the field of phenomena. 83 He was spiritually akin to Goethe, also, in that he guarded himself strictly against substituting for the contents of our perception conveyed by Nature purely hypothetical entities which, while fashioned after the world of the senses, are, in principle, imperceptible. 84 Mayer sought after a truly empirically founded concept of force, and his method was that of reading from all the various manifestations of force which were open to sense observation. 85 One such manifestation, capable of empirical determination, was the balance between appearing and disappearing energy.

86 Science treated Mayer in the same way as it treated Howard. It took from him what it wanted for its purpose without concerning itself with the epistemological principle which had led him to his discovery. 87 Thus it was that Mayer's discovery led to most important consequences for the development of modern technical devices, whereas it was the fate of his guiding idea to be first derided, then misunderstood and finally forgotten. 88 The consequence was that the knowledge of the numerical equilibrium between created and expended energy in

the economy of Nature has widened more and more the abyss separating spirit and matter in human life, 89 instead of leading, as indeed it might have done, to a bridging of the abyss. 90 The thought, therefore, regarding the appearing and disappearing of measurable cosmic substance, to which we are led when following Goethe's method of observing Nature, 91 stands in no sort of contradiction to what Mayer himself conceived as the relation of the various forms of energy to one another, and the maintenance of the numerical balance between them.

92 Having thus determined our standpoint with regard to the thermodynamic theory of heat and the law of conservation, we may proceed to the study, first of the phenomenon of thermal expansion, 93 and then of the effect of heat on the various states of physical matter, by applying to them, unimpeded by any preconceived mechanistic idea, what we have learn't through our previous studies. 94 We must start by developing a proper picture of the dynamic condition of matter in the solid state. 95 In a solid body the material substance is centred on an inner point, the so-called centre of gravity-- a characteristic which such a body shares with the earth as a whole. 96 Likewise, two such bodies exert on one another the same influence that the earth exerts on each of them: they try to assume the shortest possible distance from each other.

97 Since the days of Faraday science has been accustomed to ascribe these phenomena to the existence of certain fields of force, connected with each body and working on one another through the intermediary space. 98 It is to this concept of the field of force that we must now give special attention. For the field-concept, in the form introduced by Faraday into scientific thinking, 99 is one of the few scientific concepts which have been obtained by being 'read' from the corresponding phenomena themselves, and which therefore retain their validity in a science which is based on the method of reading.

100 According to the field-concept, terrestrial manifestations of gravity are due to the earth's being the

bearer of a gravitational field centred within the globe, and extending thence in all directions through space, across and beyond the earth's body. 101 Every point in space, both inside and outside the earth, is characterised by a definite intensity of this field, the so-called gravitational potential. 102 This is subject to variations due to the presence of other physical masses, which carry their own fields of gravity. 103 What happens between such masses and that of the earth, as well as mutually between such masses themselves, is brought about by the particular conditions in space resulting from the interpenetration of the various fields.

104 It is essential to realise that all fields dealt with by physical science, the gravitational, electric, magnetic-- however much they differ otherwise-- have this one characteristic in common, 105 that they have a centre where the field is at its highest intensity, diminishing as the distance from the centre increases. 106 Motion in such a field naturally takes place from regions of lower to those of higher intensity-- in other words, it follows the rising potential of the field. 107 This accounts for the tendency of physical masses to arrive at the shortest possible distance between them.

108 It was natural for the modern mind to picture a dynamic condition of the kind just described, 109 that is, one in which the centre and source, as it were, is a point round which the dynamic condition spreads with steadily diminishing strength as the distance from the point grows. 110 For such is the condition of human's head-bound consciousness. The locus from which modern human watches the world is a point within the field of this consciousness, and the intensity with which the world acts on it diminishes with increasing spatial distance from this point. 111 This is the reason why levity was banished from scientific inquiry, and why, when the field-concept was created by the genius of Faraday, it did not occur to anyone that with it the way was opened to comprehend field-types other than the centric one characteristic of gravity and kindred forces. 112 To make use of the field-concept in

this other way is one of the tasks we have to undertake if we are to overcome the impasse in which present-day scientific cognition finds itself.

113 To develop a picture of the type of field represented by levity, let us recall certain results from the observations of the last chapter.

114 There the volcanic phenomenon, when taken in its wider implications, made us realise that the upward movement of physical masses, in itself part of the total phenomenon, is due to a dynamic cause which we had to describe, in contrast to centripetally working pressure, as peripherally working suction. 115 Of this concept of suction we must now observe that we may apply it with justification only if we realise that suction can be caused in two different ways. 116 In the sense in which we are wont to use the term, suction is the result of a difference of pressure in adjacent parts of space, the action taking place in the direction of the minor pressure. 117 Apart from this, however, suction can occur also as a result of the outward-bound increase of the strength of a levity-field.

118 It is in this sense that we may speak of the seismic movements of the earth as being caused by suction acting from without. 119 In the same sense we may say that the upward movement of the saps in the plant (to which Ruskin pointed as being responsible for the apple appearing at the top of the tree) 120 and with it the entire growth-phenomenon in the plant world, is due to peripheral suction.

121 Considerations of this kind lead one to a picture in which the earth is seen to be surrounded and penetrated by a field of force which is in every respect the polar opposite of the earth's gravitational field. 122 As the latter has its greatest intensity at its centre, which is identical with the centre of the earth's globe, so has the levitational field its greatest intensity at its circumference which is somewhere in the width of the universe. 123 Later considerations will enable us to locate its position more precisely.

124 As the gravity-field decreases in strength with increasing distance from the centre of the

field, that is, in the outward direction, so does the levity-field decrease in strength with increasing distance from its periphery, or in the inward direction. 125 In both fields the direction of movement is from regions of lower to those of higher intensity. This is why things 'fall' under the influence of gravity and 'rise' under the influence of levity.

126 How does thermal expansion read as a letter in Nature's script when seen in the light of the two contrasting field-concepts?

127 Let us, for simplicity's sake, imagine a spherically shaped metallic body, say, a ball of copper, which we expose to the influence of heat. 128 As we have seen, it is the centrically orientated gravity-field which gives the ball its permanency of shape. 129 Consequently, the dynamic orientation of the material constituting its body is directed towards the interior of the body itself.

130 Now, the moment we bring heat to bear on the body we find its surface moving in the outward direction. 131 The whole mass is clearly under the influence of some suction which is directed on to the body from outside. 132 Just as the plants grow in the anti-gravitational direction as a result of the suctional effect of levity (other factors which account for its growing into a particular shape, etc., being left out of consideration), so our copper ball grows in volume by being sucked away from its centre of gravity. 132 It is the action of heat which has changed the ratio between gravity and levity at this spot in such a way as to allow levity to produce this effect.

133 What we have thus found to be the true nature of the event perceived as a body's growth in volume under the influence of heat has a definite effect on our conception of spatially extended matter as such. 134 For a physical body is always in some thermal state which may be regarded as higher than another, and it may therefore be regarded as being at all times thermally expanded to some extent. 135 Hence, it is all the time under the sway of both gravitational pressure and anti-gravitational suction. 136 In fact, we may say ideally that, if there

were no field working inwards from the cosmic periphery, the entire material content of the earthly realm would be reduced by gravitation to a spaceless point; 137 just as under the sole influence of the peripheral field of levity it would dissipate into the universe.

138 To ordinary scientific thinking this may sound paradoxical, but in reality it is not. 139 Observation of the nature of solid matter has led atomistic thought to regard a physical body as a heap of molecules so far apart that by far the greater part of the volume occupied by the body is just 'empty' space. 140 In the scientific picture of molecules constituting a physical body, of atoms constituting the molecules, of electrons, protons, etc., constituting the atoms, all separated by spaces far exceeding the size of the elementary particles themselves, 141 we find reflected, in a form comprehensible to the onlooker-consciousness, the fact that matter, even in the solid state, is kept in spatial extension by a field of force relating it to the cosmic periphery.

142 With this picture of solid matter as being held in spatial extension by its subjection to gravity and levity alike, we proceed to a study of the liquid and gaseous states of matter, while taking into account the role of heat in bringing these states about.

143 Following out our method of seeking to gain knowledge of a phenomenon by regarding it as part of a greater whole, let us ask what sort of change a portion of physical substance undergoes in its relation to the earth as a whole 144 when, for instance, through the influence of heat, it passes from a solid to a liquid state. 145 Here we must keep in mind that it is part of the nature of a liquid to have no form of its own. The only natural boundary of a liquid substance is its upper surface. 146 Since this surface always lies parallel with the surface of the earth it forms part of a sphere, the centre point of which is identical with that of the gravitational centre of the earth. 147 The passage of a portion of matter from solid to liquid thus signifies that it ceases to possess a centre of gravity of its own and is now merely obedient to the

general gravity-field of the earth. 148 We can thus speak of a transition of matter from the individual to the planetary condition. This is what heat brings about when a solid body melts.

149 A large part of the heat used in melting is known to be absorbed by the substance during the process of melting. 150 This is indicated by the thermometer remaining at the temperature of the melting-point once this has been reached, until the whole of the melting substance has liquefied. 151 Physics here speaks of 'free' heat becoming 'latent'. From the Goethean point of view we see heat passing through a metamorphosis. 152 Whereas, previously, heat was perceptible to our sense of warmth, it now manifests as a gravity-denying property of matter.

153 In order to obtain an idea of the liquid state of matter corresponding to reality, we must take into account yet another of its characteristics. 154 When the heat becomes latent, it goes even further in contradicting gravity than by robbing matter of its own point of gravity and relating it to the earth's centre of gravity. 155 This effect is shown in the well-known urge of all liquids to evaporate. Hence we must say that even where matter in a liquid state preserves its own surface, this does not by any means represent an absolute boundary. 156 Above the surface there proceeds a continuous transition of substance into the next higher condition through evaporation. We see here the activity of heat going beyond the mere denial of gravity to a positive affirmation of levity.

157 With the help of this conception of the integration of the liquid state within the polarity of gravity and levity, we are now able to draw a picture of the earth which, once obtained, answers many a question left unanswered by current scientific notions, 158 among them the question why the earth's volcanic activity is confined to maritime regions.

159 Regarding the distribution of land and water on the earth's surface, we may say that to an observer in cosmic space the earth would not look at all like a solid body. 160 Rather would it appear as a gigantic 'drop' of water, its

surface interspersed with solid formations, the continents and other land masses. 161 Moreover, the evidence assembled ever since Professor A. Wegener's first researches suggests that the continents are clod-like formations which 'float' on an underlying viscous substance and are able to move (very slowly) in both the vertical and horizontal directions. 162 The oceanic waters are in fact separated from the viscous substratum by no more than a thin layer of solid earth, a mere skin in comparison with the size of the planet. 163 Further, this 'drop' of liquid which represents the earth is in constant communication with its environment through the perpetual evaporation from the ocean, as well as from every other body of water.

164 This picture of the earth shows it lying under the two-fold influence of the compressive force of gravity and the sucking force of levity. 165 Wherever land meets sea, there levity tends to prevail over gravity. 166 It is in maritime regions, accordingly, that the inner strata of the earth succumb most readily to those sudden changes in the gravity-levity tension wherein we have recognised the origin of seismic occurrences.

167 Turning to the gaseous condition, we realise that although even here matter retains traces of a connexion with terrestrial gravity, levity is now the dominant factor. 168 There are three characteristics of the gaseous condition which bring this out. One is the extreme readiness of gases to expand when heated; 169 we see here how much easier than with solid substances it is for heat to overcome the influence of gravity.

170 The second characteristic is the property of gases, peculiar to them, of expanding spontaneously, even when not heated. 171 Here we find gaseous matter displaying a dynamic behaviour which at lower stages occurs only under the stimulus of heat. 172 The third characteristic is shown by the fact that all gases, unlike solids or liquids, respond with the same increase of volume to a given rise of temperature, however diverse their other qualities may be. 173 Once gases are mixed, therefore, they cannot be separated merely by raising or lowering the

temperature. Here we find the unifying effect of the cosmic periphery prevailing over the differentiating effect of terrestrial gravity.

174 At this point we may recall Goethe's reply to the botanist, Wolff, who had ascribed the metamorphosis of plant-organs from root to blossom to a gradual stunting or atrophy of their vegetative force, 175 whereas it was clear to Goethe that simultaneously with a physical retrogression, there is a spiritual progress in the development of the plant. 176 The fact that all Wolff's efforts to see clearly did not save him from 'seeing past the thing' seemed to Goethe an inevitable result of Wolff's failure to associate with the eyes of the body those of the spirit.

177 Exactly the same thing holds good for the sequence of physical states of matter which we are considering here. 178 Observation of this sequence with the bodily eyes alone will show nothing but a reduction of the specific gravity of the material concerned. 179 He who is at pains to observe also with the eye of the spirit, however, is aware of a positive increase of lightness going hand in hand with a decrease of heaviness. 180 Regarded thus, the three ponderable conditions form what Goethe would have called a 'spiritual ladder'. 181 As 'rungs' of such a ladder they clearly point to a fourth rung-- that is, a fourth state in which levity so far prevails over gravity that the substance no longer has any weight at all. 182 This picture of the fourfold transformation of matter calls for an inquiry into the transition between the third and fourth states, corresponding to the well-known transitions between the three ponderable states.

183 Our observations have led us to a concept of heat essentially different from that held by modern science. Science looks on heat simply as a condition of ponderable matter. 184 We, on the contrary, are led to recognise in heat a fourth condition into which matter may pass on leaving the three ponderable conditions, and out of which it may emerge on the way to ponderability. 185 Before showing that such transitions are actually known in Nature, it may

be well to discuss here an objection which the customary way of thinking might plausibly advance against our whole method. 186 It could be said that to assume a continuation of the sequence of the three ponderable conditions in the manner suggested is justified only if, 187 as solids can be turned into liquids and these into gases, so gases could be transformed into a fourth condition and, conversely, be produced from the latter.

188 In reply it can be said that the fact of our not being able at present to change gases artificially into pure heat does not justify the conclusion that this is in principle impossible. 189 We know from previous considerations that the earth has reached an evolutionary stage at which all elements, including fire, have in certain degree grown 'old'. 190 This applies in quite a special degree to the manipulations to which human, led by your death-bound consciousness, has learn't to submit matter in your laboratories. 191 To decide what is possible or not possible in Nature, therefore, can by no means be left to the judgment of laboratory research. 192 As is shown by the following instance, taken from the realm of vegetable life, a case of the creation of matter 'out of nothing' is already known to biology-- 193 though biology, bound in its concepts to the Law of Conservation, shows some natural reluctance to recognise the true significance of the phenomenon.

194 The plant which performs this strange feat is the Tillandsia usneoides, indigenous to tropical America, and generally known as 'Spanish Moss'. 195 Its peculiarity is that it grows and flourishes without taking from its support any material whatsoever for the building up of its substance. Its natural habitat is the dry bark of virgin forest trees. 196 Since civilisation invaded its home it has acquired the habit of growing even on telegraph wires, which has given it the popular name of 'telegraph tresses'. 197 Chemical analysis of this plant shows the presence of an average of 17 per cent iron, 36 per cent silicic acid and 1Â·65 per cent phosphoric acid. 198 This applies to samples taken from districts where the

rainwater-- the only source from which the plant could extract these substances in physical form-- contains at most 1Â·65 per cent iron, 0Â·01 per cent silicic acid and no phosphoric acid at all.

199 The Tillandsia phenomenon is to a certain extent reminiscent of another well-known plant activity. This is the process of assimilation of carbon from the carbon dioxide of the air. 200 If we leave aside the change in the chemical combination which the carbon undergoes, there remains the picture of the plant drawing this matter to itself from its environment and at the same time subjecting it to a spatial condensation. 201 A similar but even more far-reaching process is exhibited by the Tillandsia as regards the three substances referred to above. 202 From the conditions given, it follows that the plant cannot possibly get these substances elsewhere than out of the surrounding atmosphere, and that in drawing upon them it submits them to a high degree of condensation. 203 A special role, however, is played by the phosphorus, which shows that the assimilative power of the plant is sufficient to transform phosphorus from a physically not traceable state into one of spatially bounded materiality. 204 Following Goethe in his coining of the concept of 'spiritual anastomosis' for the pollinating process of plants, we can here speak of 'spiritual assimilation'.

205 In this respect Tillandsia provides an instance 'worth a thousand, bearing all within itself. 206 For what Nature here unmistakably demonstrates serves as an eye-opener to a universal fact of the plant kingdom and of Nature in general. The problem of the so-called trace-elements may serve as an illustration of this.

207 Modern agricultural chemistry has found of a number of chemical elements that their presence in the soil in scarcely traceable amounts is necessary in order to enable the plant to unfold healthily its latent characteristics. 208 All sorts of deficiencies in cultivated plants have led to a recognition that the soil is impoverished of certain elements by intensive modern cultivation, and that it is to the lack of these elements that the

deficiencies are due. 209 Much work has meanwhile been done in classifying the various deficiencies and in devising ways of giving the soil chemical substitutes for what is lacking.

210 A large part of the work here involved could be saved were it only to be acknowledged that the soil owes the natural occurrence of the proper elements to a process which the plants themselves bring about in the soil, 211 if men refrain from hindering them by cleverly thought-out methods of cultivation which fail to reckon with the nature of a living organism.

212 Let us be clear what it is that occurs when a plant exhibits any of the observed abnormalities. Expressed in a Goethean manner, these are the consequence of an insufficient direction of the organic processes in the plant body by the spiritual plant-type underlying it. 213 That which Ruskin called the 'spirit' of the plant, and to which he drew attention in his aphorism 'Stand by Form against Force'-- by 'form' all the peculiar qualities of the plant are to be understood,-- is unable to express itself in full measure. 214 Now we know that, in order to unfold its activities on the physical plane, spirit requires 'young' matter-- that is, matter which is either in, or has just emerged from, a purely dynamic state. 215 Normally a definite spiritual type co-ordinates the dynamic functions present in the super-physical sphere of Nature in the manner required to give the plant-organism its appropriate form. 216 As, through the action of the type, these functions are brought down from the sphere of levity into that of gravity, 217 they condense to the corresponding material elements and thus reach the soil in material form via the physical organism of the plant.

218 The pattern as usually seen is now reversed; the presence of the various elements in the soil no longer appears as the origin of one or another function in the building up of the plant-body, but quite the reverse. 219 The functions appear now as the cause, and the soil-elements as the effect. 220 We may thus recognise the value of the latter as symptoms from which we can read the existence of a healthy connexion between the plant and

the corresponding form-creating functions working on it from its surroundings.

221 With this reversal of the relationship between cause and effect it is not, however, intended to represent the commonly accepted order of things as entirely incorrect. 222 In the realm of life, cause and effect are not so one-sidedly fixed as in the realm of mechanical forces. 223 We may therefore admit that a reverse effect of the soil-elements upon the plant does take place. 224 This is plainly demonstrable in the case of phosphorus which, however, by reason of its appearance in the soil in proportions hardly to be called a mere 'trace', represents a borderline case. 225 What may apply within limits to phosphorus is wholly valid for the trace-elements-- namely, that they are playing their essential role while they are themselves about to assume ponderable form. 226 It thus becomes clear how mistaken it is to attempt to cure deficiencies in plants by adding to the soil chemical substitutes for the trace-elements. 227 In the condition in which this material is offered to the plant, it is truly 'old' material. In order to be able to use it functionally, the plant has first to convert it into the 'young' condition. 228 This indeed happens whilst the material is rising in the plant combined with the juices drawn by the plant from the soil under the influence of levity-force. 229 Only when this has occurred are the chemical elements able to serve the plant functionally. Thus, by trying to give help to the plant in this way, we injure it at the same time. 230 For by forcing it to perform the operation described, its general life-forces are diminished. A seeming success brought about in this manner, therefore, will not last long. 231 There is, nevertheless, a way of helping the plant by adding to the soil certain material substances, provided these are first brought into a purely dynamic condition. 232 That this can be done is a fact long since known, even if not recognised in its true significance. So far then, as serves the purpose of this book, we shall deal with it here.

233 The method in question is associated with the school of

medicine known as Homoeopathy, founded by the German doctor, Hahnemann. 234 The word 'homoeopathy' means 'healing through like'; the basic principle is to treat disease symptoms with highly diluted substances which produce similar symptoms if ingested in normal quantity. 235 Experience has in fact shown that the physiological effect of a substance taken from external Nature is reversed when the substance is highly diluted.

236 The method of diluting, or 'potentising', is as follows: A given volume of the material to be diluted is dissolved in nine times its volume of distilled water. The degree of dilution thus arrived at is 1:10, usually symbolised as Ix. 237 A tenth part of this solution is again mixed with nine times its bulk of water. The degree of dilution is now 1:100, or 2x. This process is continued as far as is found necessary for a given purpose. 238 Insoluble substances can be dealt with in the same manner by first grinding them together with corresponding quantities of a neutral powder, generally sugar of milk. 239 After a certain number of stages the powder can be dissolved in water; the solution may then be diluted further in the manner described. 240 Here we have to do with transfer of the quality of a substance, itself insoluble, to the dissolving medium, and then with the further treatment of the latter as if it were the original bearer of the quality concerned. 241 This fact alone shows that potentisation leads into a realm of material effects at variance with the ordinary scientific conception of matter. 242 Moreover, we can carry the dilutions as far as we please without destroying the capacity of the substance to produce physiological reactions. 243 On the contrary, as soon as its original capacity is reduced to a minimum by dilution, further dilution gives it the power to cause actually stronger reactions, of a different and usually opposite kind. 244 This second capacity rises through stages to a variable maximum as dilution proceeds.

245 A simple calculation shows-- if we accept the ordinary scientific view as to the size of a molecule-- that not a single molecule of the

original substance will remain in the solution after a certain degree of dilution has been reached. 246 Yet the biological and other reactions continue long after this, and are even enhanced. 247 What this potentising process shows is that, by repeated expansions in space, a substance can be carried beyond the ponderable conditions of matter into the realm of pure functional effect. 248 The potentising of physical substances thus gains a significance far wider than that of its medical use. 249 There opens up, for example, the possibility of stimulating deficient functions in the plant by giving it the corresponding elements in homoeopathic doses. 250 By this means the plant is brought into direct connexion with the relevant spiritual energy, and then left to carry out for itself the necessary process of materialisation, instead of being forced by mere chemical additions to the soil first to potentise the substance itself.

251 The same principle holds good for human and beast. They also need 'young material' for their nourishment, 252 so that the type active in them-- which in animals is the group-soul of the species and in human is the single individual-- can express its true form and character. 253 We saw earlier that the will requires 'young' material in order to penetrate into the material layers of the muscles, as happens when the limbs are set in motion. 254 In this respect, the difference between ensouled creatures and plants is that, what is harmful to plants is natural for humans and animals: 255 when taking nourishment the latter are able to bring about quickly and purposefully a transformation of matter into the purely dynamic state. 256 Their metabolic system is designed to enable them to take alien material from outer Nature and to transform it through the forces of the various digestive enzymes; in the course of this process the material passes through a condition of complete 'chaos'.

257 Having in this way established the existence of certain processes of materialisation and dematerialisation in single organisms within the earth's vegetable and other kingdoms, 258

we shall now turn to the earth as a whole to find out where-- organic being that she herself is-- she manipulates corresponding processes on a macrotelluric scale.

259 In an age following van Helmont's discovery of the gaseous state of matter and the statement of the Contra Levitatem maxim, 260 humans were bound to think that the circulation of atmospheric moisture was limited to the three stages of liquid, vaporous (peculiar to the clouds, etc.) and the invisible aeriform condition. 261 Yet the role played by clouds in the myths of early peoples shows that they were once given a quite different status, between the 'created' and 'uncreated' worlds. 262 Our observations lead to a corresponding conception, but along the path of knowledge, guided by sense-perception, as befits our own age.

263 In discussing Howard's discovery of the stages of cloud-formation we found something lacking, 264 for it was clear that the three stages of cloud proper-- stratus, cumulus and cirrus-- have a symmetry which is disturbed by the addition of a fourth stage, represented by the nimbus. 265 This showed that there was need for a fifth stage, at the top of the series, to establish a balanced polarity. We can now clear up this question of a fifth stage, as follows.

266 In the three actual cloud-forms, gravity and levity are more or less in equilibrium, but in the nimbus gravity predominates, and the atmospheric vapour condenses accordingly into separate liquid bodies, the drops of rain. 267 The polar opposite of this process must therefore be one in which cloud-vapour, under the dominating influence of levity, passes up through a transitional condition into a state of pure heat.

268 Such a conception by no means contradicts the findings of external research. For meteorology has come to know of a heat-mantle surrounding the earth's atmosphere for which various hypothetical explanations have been advanced. 269 Naturally, none of them envisages the possibility of atmospheric substance changing into the heat-condition and back again. 270 But if we learn to look

on the chain of cloud-forms as a 'spiritual ladder', then we must expect the chain to conclude with a stage of pure heat, lying above the cirrus-sphere.

271 The line of consideration pursued in the last part of this chapter has led us from certain observations in the plant kingdom, 272 concerning the coming into being of ponderable matter from 'nothing', to a corresponding picture of the earth's meteorological sphere. 273 When discussing the plant in this respect we found as an instance 'worth a thousand, bearing all within itself the case of Tillandsia and more particularly the surprising appearance of phosphorus in it. 274 Now, in the meteorological realm it is once more phosphorus which gives us an instance of this kind. 275 For there is the well-known fact of the presence of phosphorus in conspicuous quantities in snow without a source being traceable in the atmosphere whence this substance can have originated in ponderable condition. 276 The phosphorus appearing in snow, therefore, brings before our very eyes the fact that the heights of the atmosphere are a realm of procreation of matter. 277 In our next chapter we shall learn what it is in phosphorus that makes it play this particular role in both fields of Nature. What interests us in the present context is the fact itself.

278 The knowledge we have now gained concerning the disappearance and appearance of physical water in the heights of the atmosphere will enable us to shake off one of the most characteristic errors to which the onlooker-consciousness has succumbed in its estimation of Nature. 279 This is the interpretation of thunderstorms, and particularly of lightning, which has held sway since the days of Benjamin Franklin. 280 Before developing our own picture of a thunderstorm let us recognise that science has found it necessary to reverse the explanation so long in Vogue. 281 Whereas it was formerly taken for granted-- and the assumption was supposed to rest upon experimental proof-- that the condensing of atmospheric vapour which accompanied lightning was the consequence of a release of electrical tension by the lightning,

282 the view now held is that the electrical tension responsible for the occurrence of lightning is itself the effect of a sudden condensing process of atmospheric moisture.

283 The reason for this uncertainty is that the physical conditions in the sphere where lightning occurs, according to other experiences of electric phenomena, actually exclude the formation of such high tensions as are necessary for the occurrence of discharges on the scale of lightning. 284 If we look at this fact without scientific bias we are once again reminded of the Hans Andersen child. 285 We cannot help wondering how this child would behave in a physics class if the teacher, after vainly trying to produce a lightning-flash in miniature with the help of an electrical machine, 286 explained that the moisture prevalent in the air was responsible for the failure of the experiment, and that he would have to postpone it to a day when the air was drier. 287 It would scarcely escape the Hans Andersen child that the conditions announced by the teacher as unfavourable to the production of an electric spark by the machine, prevail in a much higher degree exactly where lightning, as a supposed electric spark, actually does occur.

288 To conclude from the presence of electric tensions in the earth's atmosphere as an accompaniment of lightning, in the way first observed by Franklin, 289 that lightning itself is an electrical process, is to be under the same kind of illusion that led people to attribute electrical characteristics to the human soul because its activity in the body was found to be accompanied by electrical processes in the latter. 290 The identification of lightning with the electric spark is a case of a confusion between the upper and lower boundaries of Nature, characteristic of the onlooker-consciousness. 291 As such, it has stood in the way of a real understanding both of non-electrical natural phenomena and of electricity itself.

291 What we observe in lightning is really an instantaneous execution of a process which runs its course continually in the atmosphere, quietly and unnoticed. 292 It is the process by which

water reverts from the imponderable to the ponderable condition, after having been converted to the former through levity set in action by the sun-- as usually happens in a high degree just before a thunderstorm. 293 We form a true picture of the course of a storm if we say that Nature enables us to witness a sublime display of the sudden bringing to birth of matter in earthbound form. 294 What falls to the ground as rain (or hail) is substantially identical with what was perceptible to the eye, a moment before, as a majestic light-phenomenon. 295 The accompanying electrical occurrence is the appropriate counter-event at Nature's lower boundary. 296 Since the two form part of a larger whole they necessarily occur together; but the electrical occurrence must not be identified with the event in the heavens. 297 The reason for their conjunction will become clear later, when we shall show how electrical polarity arises from the polarity between gravity and levity.

298 If one learns to view a thunderstorm in this way, its spiritual connexion with the earth's volcanic processes becomes manifest; there is in fact a polar relationship between them. 299 For just as in volcanic activity heavy matter is suddenly and swiftly driven heavenwards under the influence of levity, so in a storm does light matter stream earthwards under the influence of gravity.

300 It is this combination of kinship and polar opposition which led people of old to regard both lightning in the heights and seismic disturbances in the depths as signs of direct intervention by higher powers in the affairs of humans. 301 A trace of this old feeling lingers in the Greek word Î¸ÎµÎ¹Î¿Î½ (theion), divine, which was used to denote both lightning and sulphur. Influenced by the same conception, 302 the Romans regarded as holy a spot where lightning had struck the earth; they even fenced it off to protect it from human contact. 303 Note in this respect also the biblical report of the event on Mount Sinai, mentioned before, telling of an

interplay of volcanic and meteorological phenomena as a sign of the direct intervention of the Godhead.

MATTER
AS PART OF NATURE'S ALPHABET
Ernst Lehrs

11 In the preceding chapter we drew attention to the fact that any spatially extended mass is under the sway of both gravity and levity. 2 We then saw that with the transition of matter from the solid via the liquid to the gaseous state, not only does the specific gravity of the substance decrease, but at the same time an increase takes place of what we might call 'specific levity'. 3 In the gaseous state, therefore, we find gravity-bound matter becoming so far levity-bound that it assumes the property of actively expanding in space.

4 Having once adopted the Goethean way of thinking-in-polarities, we may feel sure that there is somewhere in Nature a phenomenon which represents the polar opposite of the levity-gravity relationship peculiar to the gaseous state. 5 In this latter state we find ponderable matter so far brought under the sway of levity that its behaviour is of a kind which van Helmont, when he first observed it, could not help describing as 'paradoxical'. 6 Where, we must now ask, do we find imponderable essence so much under the sway of gravity that it shows the correspondingly paradoxical features? 7 In other words, where does Nature show levity concentrated in a limited part of space-- that is, in a condition characteristic of ponderable matter? 8 Such concentrations of levity do indeed exist in varied forms. One is the 'warmth-body' represented by the blood-heat of the higher animals and human. 9 There is, however, an occurrence of this kind also on the purely mineral level of Nature, and it is this which has particular significance for our present study of matter. We meet it in all physical substances which have the peculiarity of being combustible.

10 Our next task is to study certain fundamentals in regard to the

different ways in which levity and gravity are found to be intertwined in combustible substances, 11 manifesting through the difference of their relation to the process of combustion-- that is, the process by which levity is restored to its original condition. 12 It is the aim of the present chapter to show that by doing justice to the imponderable aspect of combustion, the way is opened to a view of the 'elements', as scientific chemistry understands them, which will be in line with our dynamic conception of matter. 13 There is nothing surprising in the fact that a new conception of the chemical element can arise from a re-study of the process of combustion, 14 if we remember that it was the picture of combustion, characteristic of the spectator-consciousness, which determined the conception of the chemical element as it prevails in modern science. 15 Let us see how this conception came to pass historically in order to find where we stand to-day.

16 With the establishment of the knowledge of a state of physical matter which, as the definition ran, 'neither results from a combination of other physical substances nor is resolvable into such', the conviction arose that human's searching mind had reached 'rock-bottom'. 17 This conviction, however, was shaken when, with the discovery of radium, an element became known whose property it is to disintegrate into two other elements, helium and lead. 18 Although this did not force science to abandon the element-concept altogether, it became necessary to find a new definition for it.

19 This definition was established by Professor W. Ostwald at the beginning of the present century, when he stated that the chemical element represents a condition of physical matter in which 'any chemical change results in an increase of weight'. 20 In this way, the chemical concept of the element achieved a meaning which had actually been implicit in it from its first conception. 21 For its very formation had been the outcome of the Contra-Levitatem maxim. The following glance over the history of chemistry will show this.

22 The birth of chemistry as a science, in the modern sense, is closely connected with a revolutionary change in the conception of what can be called the chemical arch-process-combustion, or, to use a more scientific term, oxidation. 23 This change arose out of the Contra-Levitatem maxim and the new conception of heat which this maxim required. 24 In the old doctrine of the four Elements, Heat had been conceived as a manifestation of the element of Fire, and so, together with Air, as belonging to the realm of the 'uncreated things'. 25 Hence the release of heat from created substance was always felt to be a sacred act, as is shown by the fire rites of old.

26 Modern human's conception of the same process is revealed in the answer one invariably receives from both layman and scientist when they are asked what they understand by combustion. 27 It is described as a process through which oxygen combines with the combustible substance. 28 And yet this side of combustion, first observed by J. Priestley (1771), is neither the one for the sake of which human produces combustion in the service of own everyday life, nor is it at all observed by ordinary sense-perception. 29 Nevertheless, to describe the obvious fact, that combustion is liberation of heat from the combustible substance, will hardly occur to anyone to-day. 30 This shows to what extent even the scientifically untrained consciousness in our time turns instinctively to the tangible or weighable side of Nature, so that some effort is required to confess simply to what the eye and the other senses perceive.

31 During the first hundred years after the establishment of the Contra-Levitatem maxim, human's situation was in a certain sense the opposite of this. 32 Then, people were struggling hard to get away from the old concept which saw in combustion nothing but the liberation of a super-terrestrial element from earthly fetters. 33 This struggle found expression in a theory of heat which at that time greatly occupied scientific thinking. It is the so-called

phlogiston-theory first proposed by the chemist Stahl (1660-1734).

34 This theory reveals the great uncertainty into which human's thinking about the world of the senses had arrived at that time. 35 Clinging to ideas inherited from antiquity, human's consciousness was already so far restricted to the forming of pure matter-bound concepts that one was tempted to conceive heat as a material element. 36 To this heat-substance the name 'phlogiston' was given. 37 At the same time, under the Contra-Levitatem maxim, it was impossible to conceive of substance except as ponderable substance. 38 This led to the conviction that whenever heat appears as a result of some treatment of matter-- combustion or friction,-- the material substance subject to this treatment must lose weight.

39 The experiments of Lavoisier (1743-94), which he undertook following Priestley's discovery of the role of oxygen in combustion, put an end to this theory. These experiments are rightly regarded as the actual beginning of modern chemistry. 40 In Lavoisier we find an observer of Nature who was predominantly interested in what the scales could tell about changes in substances. It was from this aspect that he investigated the process of oxidation. 41 What had already been observed by a few others, though without being taken seriously by them, he found confirmed-- that, contrary to the phlogiston-- theory, matter does not lose weight through oxidation but gains weight. 42 Further experiments proved beyond doubt that in all chemical reactions the total weight of the components remained constant. 43 However much the substance resulting from the chemical reaction of others might differ from these, its weight always proved to be the same as their total weight. 44 What else could be concluded from the apparent unchangeability of weight throughout all the chemical happenings in Nature than that the ponderable world-content was of eternal duration? 45 We see here how much modern chemistry and its concept of the chemical element has been ruled right from the start by the one-sided gravity

concept of the onlooker-consciousness.

46 Together with the overcoming of the fallacy that heat is a ponderable substance (full certainty was indeed established only some time later through the investigations of Davy and Rumford into heat generated by friction)-- 47 human thinking was led into a one-sided conception of combustion which was merely the opposite of the one held earlier. 48 Whereas formerly human's mind was pre-eminently occupied by the liberation of the imponderable element through combustion, it now turned entirely to what goes on in the ponderable realm.

49 As we have seen, one outcome of this one-sided view of combustion was the modern concept of the chemical element. 50 To-day our task is to overcome this concept by taking a step corresponding to the one that led to it, that is, by a study of combustibility which does justice to both sides of the process involved.

51 As objects of our observation we choose three chemical elements all of which have the property of combustibility: Sulphur, Phosphorus, and Carbon. 52 As will become clear, our choice of these three is determined by the fact that together they represent an instance 'worth a thousand, bearing all within itself.

53 We begin by comparing Sulphur and Phosphorus. In their elementary state they have in common the fact that any chemical change is bound up with an increase in their weight. 54 In this state both are combustible. Apart from this similarity, there is a great difference between them, as the way of storing them illustrates. 55 For while elementary sulphur needs only an ordinary container, phosphorus has to be kept under cover of water in order to prevent the atmospheric oxygen from touching it. 56 The reason is that the combustible state is natural for sulphur, but not for phosphorus, the latter's natural state being the oxidized one. 57 This different relationship of sulphur and phosphorus to the oxidizable (reduced) and the oxidized state manifests itself in all their chemical reactions.

58 To object here that the different reactions of the two substances are due only to the difference of their respective temperatures of ignition, 59 and that above these temperatures the difference will more or less disappear-- all combustible substances at a sufficiently high temperature becoming more or less similar to phosphorus,-- would not meet the argument. 60 For what matters here is just how the particular substance behaves at that level of temperature on which the earth unfolds her normal planetary activity. 61 To ignore this would be to violate one of the principles we have adopted from Goethe, which is never to derive fundamental concepts of Nature from observations obtained under artificial conditions.

62 Sulphur and phosphorus are thus seen to represent two polarically opposite tendencies with regard to the levity-gravity coherence which breaks up when combustion occurs. 63 In the case of sulphur, the ponderable and imponderable entities appear to cling together; in the case of phosphorus, they seem to be anxious to part. 64 These two different tendencies-- which are characteristic of many other substances and represent a basic factor in the chemical happenings of the earth-- are in their own way a pair of opposites. 65 Since each of them represents in itself a relationship between two poles of a polarity-gravity and levity-- so in their mutual relationship they represent a 'polarity of polarities'. 66 In Fig. 4 an attempt has been made to represent this fact by a symbolic diagram.

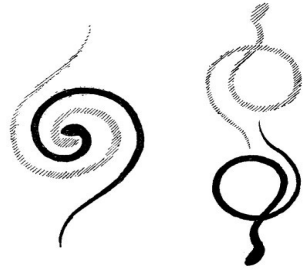

FIG. 4.

In this figure the shaded part represents the imponderable, the black part the ponderable entity. 67 In the left-hand symbol both are shown in a relationship corresponding to the one characteristic of sulphur; in the right-hand figure the relationship is characteristic of phosphorus.

68 Here we have an instance of a kind of polarity which belongs to

the fundamentals of Nature as much as does the levity-gravity polarity itself. 69 Wherever two poles of a polarity meet, they have the possibility of being connected in two ways which in themselves are again polarically opposite. 70 Our further studies will bring up various other instances of this kind, and will show us that part of the epistemological trouble in which science finds itself to-day results from the fact that the scientific mind has been unable to distinguish between the two kinds of polarity-- 71 that is, as we shall say henceforth, between polarities of the first order (primary polarities) and polarities of the second order (secondary polarities).

72 In actual fact, the distinction between the two orders of polarity has been implicit in the descriptions given in this book right from the start. 73 Remember, in this respect, how the picture of the threefold psycho-physical structure of human, which has proved a master-key for unlocking the most varied scientific problems, was first built up. 74 There, 'body' and 'soul' represented a polarity which is obviously one of the first order. By our observation of the human organism, in relation both to the different functions of the soul and to the different main organic systems, 75 we further recognised the fact that the ways in which body and soul are interrelated are polarically opposite in the region of the brain and nerves and in the region of the metabolic processes, 76 which again results in two polarically opposite activities of the soul, mental on the one hand, and volitional on the other. 77 In what we called the pole-of-consciousness and the pole-of-life we therefore have a clear polarity of the second order, and so in everything that is connected with these two, as our further discussions will show.

78 Remembering that our first occasion to concern ourselves overtly with the concept of polarity was in connexion with the four elements, 79 we may now ask whether the old doctrine did not embrace some conception of secondary polarity as well as of primary polarity, 80 and if so, whether this might not prove as

helpful in clarifying our own conceptions as was the primary polarity, cold-warm. That this is indeed so, the following description will show.

81 Beside the two qualities cold and warm the doctrine of the four elements pointed to two further qualities forming in themselves a pair of opposites, namely, dry and moist. 82 Just as the four elements were seen as grouping themselves in two pairs, Fire-Air on the one hand, Water-Earth on the other, the first being characterised by the quality warm, the second by cold, 83 so were they seen to form two opposing groups, Fire-Earth and Air-Water, of which one was characterised by the quality dry, the other by the quality moist. 84 Fig. 5 shows how the four elements in their totality were seen to arise out of the various combinations of the four qualities.

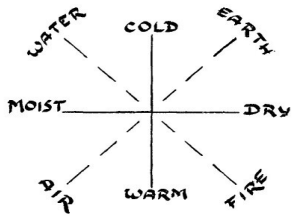

FIG. 5.

85 In this diagram the element Earth appears as a combination of the qualities Dry and Cold; Water of Cold and Moist; Air of Moist and Warm; Fire of Warm and Dry. 86 As a result, Earth and Fire, besides representing opposite poles, are also neighbours in the diagram. 87 Here we encounter a picture characteristic of all earlier ways of looking at the world: 88 the members of a system of phenomena, when ranked in due order of succession, were seen to turn back on themselves circle-wise-- or, more precisely, spiral-wise.

89 In what way do the qualities dry and moist form a polarity of the second order, 90 and how do they represent the chemical polarity characteristic of sulphur and phosphorus as well as all the other secondary polarities dealt with in this book? 91 To understand this we must submit the couple dry-moist to the same scrutiny as we applied to cold and warm in our earlier discussion of the four elements.

92 It lies in the nature of things that we instinctively associate these qualities with the solid and liquid states of matter respectively. 93 This certainly agrees with the

diagram given above, where the elements Earth and Water are distinguished precisely by their connexion with these two characteristics. 94 Yet, in addition to this, the qualities dry and moist are found to be characteristic also of Fire and Air respectively, though with the difference that they are linked not with the quality cold, as in the case of the lower elements, but with the quality warm. 95 So we see that the concepts Dry and Moist, as they lived in the old picturing of them, mean a good deal more than we understand by them to-day.

96 That these two respective attributes do not belong exclusively to the solid and the liquid states of matter can be seen at once by observing the different reactions of certain liquids to a solid surface which they touch. 97 One need only recall the difference between water and quicksilver. If water runs over a surface it leaves a trail; quicksilver does not. Water clings to the side of a vessel; again, quicksilver does not. 98 A well-known consequence of this difference is that in a narrow tube the surface of the liquid-- the so-called meniscus-- stands higher at the circumference than at the centre in the case of water; with quicksilver it is just the reverse. 99 In the sense of the two qualities, dry and moist, water is a 'moist' liquid; quicksilver a 'dry' one. 100 On the other hand, the quality of moistness in a solid substance appears in the adhesive power of glue. 101 Let us now see how, in accordance with the scheme given in Fig. 5, the four qualities in their respective combinations constitute the four elements. 102 From the description we shall give here it will be realised how little such ancient schemes were based on abstract thoughts, and how much they were read from the facts of the world. 103 Moreover, a comparison with our description of the four stages of matter, given in the previous chapter, would show how far the conceptual content of the old doctrine covers the corresponding facts 104 when they are read by the eye of the modern reader in Nature, notwithstanding the changes Nature has undergone in the meantime.

105 The element Fire reveals its attributes of warm and dry in a

behaviour which combines a tendency to dynamic expansion with a disinclination to enter into lasting combination with the other elements. 106 Correspondingly, the behaviour of the element Earth unites a tendency to contraction with an inclination to fall out of conjunction with the other elements. 107 Thus the attribute, dry, belongs equally to pure flame and sheer dust, though for opposite reasons. 108 Distinct from both these elements are the middle elements Water and Air; with them the attribute, moist, comes to expression in their tendency both to inter-penetrate mutually and to absorb their neighbours-- 109 the liquid element absorbing solid matter and the aeriform element taking up heat. 110 What distinguishes them is that water has a 'cold' nature, from which it gains its density; while air has a 'warm' nature, to which it owes its tendency to expand.

111 In the most general sense, the quality 'moist' applies wherever two different entities are drawn into some kind of intimate relationship with one another; 'dry' applies where no such relationship prevails. 112 Seen thus, they reveal themselves as a true polarity of the second order, for they describe the relationship between two entities which already exists, and, in the case of the four elements, are themselves a polarity. 113 As such, they characterise precisely those polar relationships of the second order on which the threefold structure of human, we found, is based. 114 For from the physical, as much as from the super-physical aspect the nerve-system represents the 'dry' part, and the metabolic system the 'moist' part of human's being. 115 The same is true of the relationship between the soul and the surrounding world at both poles. Here we have the antithesis between the 'dry' onlooker-relationship of the intellect to the world, 116 conceived as a mere picture whose essence remains outside the boundaries of the soul, and the 'moist' intermingling of the will-force with the actual forces of the world.

117 It needs no further explanation to realise that sulphur and phosphorus, by the way in which levity and gravity are interlinked

in each of them, are representatives of these very qualities 'moist' and 'dry'. 118 As such they are universally active bearers of these qualities in every realm of Nature's varied activities, as their physical presence in such cases confirms. 119 Consequently, sulphur is found in the protein-substances of the human body wherever they are bearers of metabolic processes, while the presence of phosphorus is characteristic of the nerves and bones. 120 Although its full significance will become clear to us only later, the fact may here be mentioned that the composition of the bone-material in the different parts of human's skeleton, as scientific analysis has shown, 121 is such that the content of phosphate of calcium in proportion to carbonate of calcium is higher in all those parts which are spherically shaped, such as the upper parts of the skull and the upper ends of the limb-bones.

122 In particular the plant reveals clearly the functional significance of phosphorus as the bearer of the quality 'dry'. 123 For its healthy growth the plant needs the quality 'dry' in two places: at the root, where it unites with the element earth, and in the flower, where it opens itself to the fire element. 124 Root and flower as distinct from the middle parts of the plant are both 'dry' formations. In a still higher degree this applies to the seed, which must separate itself from the mother plant to produce a separate new organism. 125 All these are functions in the plant which, as was mentioned in the last chapter, require phosphorus for their healthy performance. 126 Our examination of phosphorus and sulphur from the functional point of view throws light also on their effect on the alternating conditions of waking and sleeping, necessary for the life of the higher organisms. 127 This rhythmic change, which affects especially the nervous system, is an alternation between the qualities dry and moist. 128 Disturbance of this alternation in one direction or the other makes it difficult for the organism to react in full wakefulness or normal sleep. 129 It follows that treatment with phosphorus or sulphur in suitable preparations, according to

the nature of the disturbance, can be beneficial.

130 If we study the functional properties of such substances we see that they can teach us a rational understanding of therapeutic practices, which otherwise must remain mere results of trial and error. 131 The same applies to phosphorus and sulphur treatment in cases where in the functionally 'dry' bone system or in the functionally 'moist' metabolic system of the organism the wrong quality predominates. 132 If the bones remain too 'moist' there is a tendency to rickets; against this, certain fish-oils are a well-known remedy on account of their highly phosphoric nature. 133 Conversely, the application of sulphur can help where weakness of the metabolic forces produces rheumatic or gouty sediments in parts of the body whose function is to serve by their mobility the activities of the will. 134 In this case the abnormal predominance of the quality 'dry' can be counteracted by the medical application of sulphur.

135 Having observed the action of sulphur and phosphorus in the laboratory and in living organisms, we will now turn to phenomena of a macrotelluric nature which reveal the participation of sulphur and phosphorus. 136 There, sulphur points unmistakably to the earth's volcanism. It is a fact that, wherever mineral sulphur occurs in the earth, there we find a spot of former or present volcanic activity. 137 Similarly, there is no such spot on the earth without sulphur being present in one form or another. Hence the name Solfatara for the fumarole described in Chapter-9.

138 Once again it is the Solfatara which offers us a phenomenon, this time in connexion with the special role sulphur plays in its activities, which, regarded with the eye of the spirit, assumes the significance of an instance 'worth a thousand'.

139 In spite of the very high temperature of the sulphurous fumes emitted from various crevices on the edge of the Solfatara, it is possible, thanks to the complete dryness of the fumes, to crawl a little way into the interior of these crevices. 140 Not far away from the opening of the crevice, where the hot fumes touch

the cooler rock surface, one is met by a very beautiful spectacle--namely, the continual forming, out of nothing as it seems, of glittering yellow sulphur crystals, suspended in delicate chains from the ceiling. 141 In this transformation of sulphurous substance from a higher material state, nearer to levity, to that of the solid crystal, we may behold an image of the generation of matter. 142 For every physical substance and, therefore, every chemical element, exists originally as a pure function in the dynamic processes of the universe. 143 Wherever, as a result of the action of gravity, such a function congeals materially, there we meet it in the form of a physical-material substance. 144 In the same sense, sulphur and phosphorus, in their real being, are pure functions, and where they occur as physical substances, there we meet these functions in their congealed state.

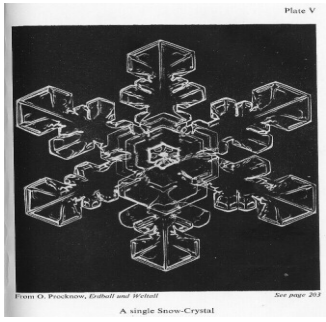
145 One of the characteristics of the volcanic regions of the earth is the healing effect of substances found there. 146 Fango-mud, for instance, which was mentioned in the last chapter, is a much-used remedy against rheumatism. This is typical of functional sulphur. 147 We may truly characterise the earth's volcanism as being qualitatively sulphurous. 148 It is the sulphur-function coming to expression through a higher degree of 'moistness' in the relationship between gravity and levity which distinguishes volcanic regions from the rest of the otherwise 'dry' earth's crust.

149 To develop a corresponding picture of the function of phosphorus, we must try to find the macrotelluric sphere where this function operates similarly to that of sulphur in volcanism. 150 From what has been said in the last chapter it will be evident that we must look to the atmosphere, as the site of snow-formation. It is this process which we must now examine more closely.

151 In the atmosphere, to begin with, we find water in a state of vapour, in which the influence of the terrestrial gravity-field is comparatively weak. Floating in this state, the vapour condenses and crystallisation proceeds. 152 Obeying the pull of gravity, more and more crystals unite in their descent and gradually form flakes

of varying sizes. The nearer they come to earth, the closer they fall, until at last on the ground they form an unbroken, more or less spherical, cover.

153 Imagine a snow-covered field glistening in the sun on a clear, quiet winter's day. As far as we can see, there is no sign of life, no movement. 154 Here water, which is normally fluid and, in its liquid state, serves the ever-changing life-processes, covers the earth in the form of millions of separate crystals shaped with mathematical exactitude, each of which breaks and reflects in a million rays the light from the sun (Plate V).

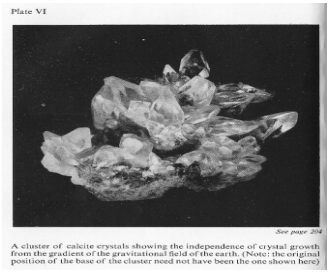


A single Snow-Crystal

155 A contrast, indeed, between this quiet emergence of forms from levity into gravity, and the form-denying volcanism surging up out of gravity into levity, as shown by the ever-restless activity of the Solfatara. 156 As we found volcanism to be a macrotelluric manifestation of functional sulphur, we find in the process of snow-formation a corresponding manifestation of functional phosphorus.

157 In the formation of snow, Nature shows us in statu agendi a process which we otherwise meet in the earth only in its finished results, crystallisation. 158 We may, therefore, rightly look upon snow-formation as an ur-phenomenon in this sphere of Nature's activities. 159 As such it allows us to learn something concerning the origin in general of the crystalline realm of the earth; 160 and, vice versa, our insight into the 'becoming' of this realm will enable us to see more clearly the universal function of which phosphorus is the main representative among the physical substances of the earth. 161 It has puzzled many an observer that crystals occur in the earth with directions of their main axes entirely independent of the direction of the earthly pull of gravity. 162 Plate VI shows the photograph of a cluster of Calcite

crystals as an example of this phenomenon.



163 It tells us that gravity can have no effect on the formation of the crystal itself. This riddle is solved by the phenomenon of snow-formation provided we allow it to speak to us as an ur-phenomenon. 164 For it then tells us that matter must be in a state of transition from lightness into heaviness if it is to appear in crystalline form. 165 The crystals in the earth, therefore, must have originated at a time when the relation between levity and gravity on the earth was different from what it is, in this sphere, to-day.

166 The same language is spoken by the property of transparency which is so predominant among crystals. One of the fundamental characteristics of heavy solid matter is to resist light-- in other words, to be opaque. 167 Exposed to heat, however, physical substance loses this feature to the extent that at the border of its ponderability all matter becomes pervious to light. 168 Now, in the transparent crystal matter retains this kinship to light even in its solid state.

169 A similar message comes from the, often so mysterious, colouring of the crystals. Here again Nature offers us an instance which, 'worth a thousand', reveals a secret that would otherwise remain veiled. 170 We refer to the pink crystals of tourmaline, whose colour comes from a small admixture of lithium. This element, which belongs to the group of the alkaline metals, does not form coloured salts (a property only shown by the heavier metals). 171 If exposed to a flame, however, it endows it with a definite colour which is the same as that of the lithium-coloured tourmaline. 172 Read as a letter in Nature's script, this fact tells us that precious stones with their flame-like colours are characterised by having kept something of the nature that was theirs before they coalesced into ponderable existence. In fact, they are 'frozen flames'.

173 It is this fact, known from ancient intuitive experience, which prompted human of old to attribute particular spiritual significance to the various precious stones of the earth and to use them correspondingly in own rituals.

174 Crystallisation, seen thus in its cosmic aspect, shows a dynamic orientation which is polarically opposite to that of the earth's seismic activities. 175 Just as in the latter we observe levity taking hold of ponderable matter and moving it in a direction opposite to the pull of gravity, so in crystallisation we see imponderable matter passing over from levity into gravity. 176 And just as we found in volcanism and related processes a field of activity of 'functional sulphur', so we found in snow-formation and related processes a field of activity of 'functional phosphorus'. 177 Both fields are characterised by an interaction between gravity and levity, this interaction being of opposite nature in each of them.

178 Here, again, sulphur and phosphorus appear as bearers of a polarity of the second order which springs from the two polarically opposite ways of interaction between the poles of the polarity of the first order: levity-gravity.

179 As in human there is a third system, mediating between the two polar systems of your organism, 180 so between sulphur and phosphorus there is a third element which in all its characteristics holds a middle place between them and is the bearer of a corresponding function. This element is carbon.

181 To see this we need only take into consideration carbon's relationship to oxidation and reduction respectively. 182 As it is natural for sulphur to be in the reduced state, and for phosphorus to be in the oxidized state, so it is in the nature of carbon to be related to both states and therefore to oscillate between them. 183 By its readiness to change over from the oxidized to the reduced state, it can serve the plant in the assimilation of light, while by its readiness to make the reverse change it serves human and animal in the breathing process. 184 We breathe in oxygen from the air; the oxygen circulates through the blood-stream and passes out again

in conjunction with carbon, as carbon dioxide, when we exhale. 185 In the process whereby the plants reduce the carbon dioxide exhaled by human and animal, while the latter again absorb with their food the carbon produced in the form of organic matter by the plant, we see carbon moving to and fro between the oxidized and the reduced conditions.

186 Within the plant itself, too, carbon acts as functionary of the alternation between oxidation and reduction. 187 During the first half of the year, when vegetation is unfolding, there is a great reduction process of oxidized carbon, 188 while in the second half of the year, when the withering process prevails, a great deal of the previously reduced carbon passes into the oxidized condition. 189 As this is connected with exhaling and inhaling of oxygen through carbon, carbon can be regarded as having the function of the lung-organ of the earth. 190 Logically enough, we find carbon playing the same role in the middle part of the threefold human organism.

191 Another indication of the midway position of carbon is its ability to combine as readily with hydrogen as with oxygen, and, in these polar combinations, even to combine with itself. 192 In this latter form it provides the basis of the innumerable organic substances in Nature, and serves as the 'building stones' of the body-substances of living organisms. 193 Among these, the carbohydrates produced by the plants show clearly the double function of carbon in the way it alternates between the states of starch and sugar.

194 When the plant absorbs through its leaves carbonic acid from the air and condenses it into the multiple grains of starch with their peculiar structure characteristic for each plant species, 195 we have a biological event which corresponds to the formation of snow in the meteorological realm. Here we see carbon at work in a manner functionally akin to that of phosphorus. 196 Sugar, on the other hand, has its place in the saps of the plants which rise through the stems and carry up

with them the mineral substances of the earth. Here we find carbon acting in a way akin to the function of sulphur.

197 This twofold nature of carbon makes itself noticeable down to the very mineral sphere of the earth. 198 There we find it in the fact that carbon occurs both in the form of the diamond, the hardest of all mineral substances, and also in the form of the softest, graphite. 199 Here also, in the diamond's brilliant transparency, and in the dense blackness of graphite, carbon reveals its twofold relation to light. 200 In Fig. 6 an attempt has been made to represent diagrammatically the function of Carbon in a way corresponding to the previous representation of the functions of Sulphur and Phosphorus.

FIG. 6.

201 By adding carbon to our observations on the polarity of sulphur and phosphorus we have been led to a triad of functions each of which expresses a specific interplay of levity and gravity. 202 That we encounter three such functions is not accidental or arbitrary. 203 Rather is it based on the fact that the interaction of forces emanating from a polarity of the first order, produces a polarity of the second order, whose poles establish between them a sphere of balance.

204 Through our study of levity and gravity in the matter-processes of the earth, a perspective thus opens up into a structural principle of Nature which is actually not new to us. 205 We encountered it at the very beginning of this book when we discussed the threefold psycho-physical order of human's being.

206 In the days of an older intuitive nature-wisdom human knew of a basic triad of functions as well as knew of the four elementary qualities. 207 We hear a last echo of this in the Middle Ages, when people striving for a deeper understanding of Nature spoke of the trinity of Salt, Mercury and Sulphur. 208 What the true alchemists, as these seekers of

knowledge called themselves, meant by this was precisely the same as the conception we have here reached through our own way of studying matter 209 'Salt' standing for 'functional phosphorus', 'Mercury' for 'functional carbon'. Only the alchemist's way was a different one.

210 This is not the place to enter into a full examination of the meaning and value of alchemy in its original legitimate sense-- which must not be confused with activities that later on paraded under the same name. 211 Only this we will say-- that genuine alchemy owes its origin to an impulse which, at a time when the onlooker-consciousness first arose, led to the foundation of a school for the development of an intuitive relationship of the soul with the world of the senses. 212 This was to enable human to resist the effects of the division which evolution was about to set up in your soul-life-- 213 the division which was to give you, on the one hand, an abstract experience of your own self, divorced from the outer world, and on the other a mere onlooker's experience of that outer world. 214 As a result of these endeavours, concepts were formed which in their literal meaning seemed to apply merely to outwardly perceptible substances, 215 while in truth they stood for the spiritual functions represented by those substances, both within and outside the human organism.

216 Thus the alchemist who used these concepts thought of them first as referring to own soul, and to the inner organic processes corresponding to the various activities of own soul. 217 When speaking of Salt they meant the regulated formative activity of their thinking, based on the salt-forming process in their nervous system. 218 When they spoke of Mercury they meant the quickly changing emotional life of the soul and the corresponding activities of the rhythmic processes of the body. 219 Lastly, Sulphur meant the will activities of your soul and the corresponding metabolic processes of the body. 220 Only through studying these functions within the self, and through re-establishing the harmony between

them which had been theirs in the beginning, and from which, you felt, 221 human had deviated in the course of time, did the alchemist hope to come to an understanding of their counterparts in the external cosmos. 222 Older alchemical writings, therefore, can be understood only if prescriptions which seem to signify certain chemical manipulations are read as instructions for certain exercises of the soul, or as advices for the redirection of corresponding processes in the body. 223 For instance, if an alchemist gave directions for a certain treatment of Sulphur, Mercury and Salt, with the assertion that by carrying out these directions properly, one would obtain Aurum (gold), 224 the alchemist really spoke of a method to direct the thinking, feeling and willing activities of the soul in such a way as to gain true Wisdom.

225 As in the case of the concepts constituting the doctrine of the four elements, we have represented here the basic alchemical concepts not only because of their historical significance, 226 but because, as ingredients of a still functional conception of Nature, they assume new significance in a science which seeks to develop, though from different starting-points, a similar conception. 227 As will be seen in our further studies, these concepts prove a welcome enrichment of the language in which we must try to express our readings in Nature.

228 Roger Bacon in the thirteenth, and Berthold Schwartz in the fourteenth century, are reputed to have carried out experiments by mixing physical salt-- in the form of the chemically labile saltpetre-- with physical sulphur 229 and-- after some initial attempts with various metals-- with charcoal, and then exposing the mixture to the heat of physical fire. 230 The outcome of this purely materialistic interpretation of the three alchemical concepts was not the acquisition of wisdom, or, as Schwartz certainly had hoped, of gold, but of ... gunpowder!

SPACE AND COUNTER-SPACE
Ernst Lehrs

12 With the introduction, in Chapter-10, of the peripheral type of force-field which appertains to levity as the usual central one does to gravity, we are compelled to revise our conception of space. 2 For in a space of a kind we are accustomed to conceive, that is, the three-dimensional, Euclidean space, the existence of such a field with its characteristic of increasing in strength in the outward direction is a paradox, contrary to mathematical logic.

3 This task, which in view of our further observations of the actions of the levity-gravity polarity in Nature we must now tackle, is, however, by no means insoluble. 4 For in modern mathematics thought-forms are already present which make it possible to develop a space-concept adequate to levity. 5 As referred to in Chapter-1, it was Rudolf Steiner who first pointed to the significance in this respect of the branch of modern mathematics known as Projective Geometry. 6 He showed that Projective Geometry, if rightly used, carries over the mind from the customary abstract to a new concrete treatment of mathematical concepts. 7 The following example will serve to explain, to start with, what we mean by saying that mathematics has hitherto been used abstractly.

8 One of the reasons why the world-picture developed by Einstein in his *Theory of Relativity* deserves to be acknowledged as a step forward in comparison with the picture drawn by classical physics, 9 lies in the fact that the old conception of three-dimensional space as a kind of 'cosmic container', extending in all directions into infinity and filled, as it were, with the content of the physical universe, 10 is replaced by a conception in which the structure of space results from the laws interrelating this content. 11 Our further discussion will show that this indeed is the way along which, to-day, mathematical thought must move in order to cope with universal reality.

12 However, for reasons discussed earlier, Einstein was forced to conceive all events in the universe after the model of gravity as

observable on the earth. 13 In this way he arrived at a space-structure which possesses neither the three-dimensionality nor the rectilinear character of so-called Euclidean space-- 14 a space-picture which, though mathematically consistent, is incomprehensible by the human mind. 15 For nothing exists in our mind that could enable us to experience as a reality a space-time continuum of three dimensions which is curved within a further dimension.

16 This outcome of Einstein's endeavours results from the fact that he tried by means of gravity-bound thought to comprehend universal happenings of which the true causes are non-gravitational. 17 A thinking that has learn't to acknowledge the existence of levity must indeed pursue precisely the opposite direction. 18 Instead of freezing time down into spatial dimension, in order to make it fit into a world ruled by nothing but gravity, we must develop a conception of space sufficiently fluid to let true time have its place therein. 19 We shall see how such a procedure will lead us to a space-concept thoroughly conceivable by human common sense, provided we are prepared to overcome the onlooker-standpoint in mathematics also.

20 Einstein owed the possibility of establishing his space-picture to a certain achievement of mathematical thinking in modern times. 21 As we have seen, one of the peculiarities of the onlooker-consciousness consists in its being devoid of all connexion with reality. 22 The process of thinking thereby gained a degree of freedom which did not exist in former ages. 23 In consequence, mathematicians were enabled in the course of the nineteenth century to conceive the most varied space-systems which were all mathematically consistent and yet lacked all relation to external existence. 24 A considerable number of space-systems have thus become established among which there is the system that served Einstein to derive his space-time concept. 25 Some of them have been more or less fully worked out, while in certain instances all that has been done is to show that they are mathematically conceivable. 26

Among these there is one which in all its characteristics is polarically opposite to the Euclidean system, and which is destined for this reason to become the space-system of levity. 27 It is symptomatic of the remoteness from reality of mathematical thinking in the onlooker-age that precisely this system has so far received no special attention.

28 For the purpose of this book it is not necessary to expound in detail why modern mathematical thinking has been led to look for thought-forms other than those of classical geometry. 29 It is enough to remark that for quite a long time there had been an awareness of the fact that the consistency of Euclid's definitions and proofs fails as soon as one has no longer to do with finite geometrical entities, 30 but with figures which extend into infinity, as for instance when the properties of parallel straight lines come into question. For the concept of infinity was foreign to classical geometrical thinking. 31 Problems of the kind which had defeated Euclidean thinking became soluble directly human thinking was able to handle the concept of infinity.

32 We shall now indicate some of the lines of geometrical thought which follow from this.

33 Let us consider a straight line extending without limits in either direction. Projective geometry is able to state that a point moving along this line in one direction will eventually return from the other. 34 To see this, we imagine two straight lines *a* and *b* intersecting at *P*. One of these lines is fixed (a); the other (b) rotates uniformly about *C*.

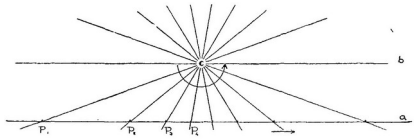


FIG. 7.

35 Fig. 7 indicates the rotation of *b* by showing it in a number of positions with the respective positions of its point of intersection with a (P1, P2. . .). 36 We observe this point moving along *a*, as a result of the rotation of *b*, until, when both lines are parallel, it reaches infinity. 37 As a result of the continued rotation of *b*, however, *P* does not remain in infinity, but returns along *a* from the other side. 38 We find here two

forms of movement linked together-- the rotational movement of a line (b) on a point (C), and the progressive movement of a point (P) along a line (a). 39 The first movement is continuous, and observable throughout within finite space. Therefore the second movement must be continuous as well, even though it partly escapes our observation. 40 Hence, when *P* disappears into infinity on one side of our own point of observation, it is at the same time in infinity on the other side. In order words, an unlimited straight line has only one point at infinity.

41 It is clear that, in order to become familiar with this aspect of geometry, one must grow together in inward activity with the happening which is contained in the above description. 42 What we therefore intend by giving such a description is to provide an opportunity for a particular mental exercise, just as when we introduced Goethe's botany by describing a number of successive leaf-formations. Here, as much as there, it is the act of 're-creating' that matters.

43 The following exercise will help us towards further clarity concerning the nature of geometrical infinity.

44 We imagine ourselves in the centre of a sphere which we allow to expand uniformly on all sides. 45 Whilst the inner wall of this sphere withdraws from us into ever greater distances, it grows flatter and flatter until, on reaching infinite distance, it turns into a plane. 46 We thus find ourselves surrounded everywhere by a surface which, in the strict mathematical sense, is a plane, and is yet one and the same surface on all sides. 47 This leads us to the conception of the plane at infinity as a self-contained entity although it expands infinitely in all directions.

48 This property of a plane at infinity, however, is really a property of any plane. To realise this, we must widen our conception of infinity by freeing it from a certain one-sidedness still connected with it. 49 This we do by transferring ourselves into the infinite plane and envisaging, not the plane from the point, but the point from the plane. 50 This

operation, however, implies something which is not obvious to a mind accustomed to the ordinary ways of mathematical reasoning. It therefore requires special explanation.

51 In the sense of Euclidean geometry, a plane is the sum-total of innumerable single points. 52 To take up a position in a plane, therefore, means to imagine oneself at one point of the plane, with the latter extending around in all directions to infinity. 53 Hence the journey from any point in space to a plane is along a straight line from one point to another. 54 In the case of the plane being at infinity, it would be a journey along a radius of the infinitely large sphere from its centre to a point at its circumference.

55 In projective geometry the operation is of a different character. Just as we arrived at the infinitely large sphere by letting a finite sphere grow, so must we consider any finite sphere as having grown from a sphere with infinitely small extension; that is, from a point. 56 To travel from the point to the infinitely distant plane in the sense of projective geometry, therefore, means that we have first to identify ourselves with the point and 'become' the plane by a process of uniform expansion in all directions.

57 As a result of this we do not arrive at one point in the plane, with the latter extending round us on all sides, but we are present in the plane as a whole everywhere. 58 No point in it can be characterised as having any distance, whether finite or infinite, from us. Nor is there any sense in speaking of the plane itself as being at infinity. 59 For any plane will allow us to identify ourselves with it in this way. And any such plane can be given the character of a plane at infinity by relating it to a point infinitely far away from it (i.e. from us).

60 Having thus dropped the one-sided conception of infinity, we must look for another characterisation of the relationship between a point and a plane which are infinitely distant from one another. 61 This requires, first of all, a proper characterisation of Point and Plane in themselves.

62 Conceived dynamically, as projective geometry requires,

Point and Plane represent a pair of opposites, the Point standing for utmost contraction, the Plane for utmost expansion. 63 As such, they form a polarity of the first order. Both together constitute Space. Which sort of space this is, depends on the relationship in which they are envisaged. 64 By positing the point as the unit from which to start, and deriving our conception of the plane from the point, we constitute Euclidean space. 65 By starting in the manner described above, with the plane as the unit, and conceiving the point from it, we constitute polar-Euclidean space.

66 The realisation of the reversibility of the relationship between Point and Plane leads to a conception of Space still free from any specific character. 67 By G. Adams this space has been appositely called archetypal space, or ur-space. 68 Both Euclidean and polar-Euclidean space are particular manifestations of it, their mutual relationship being one of metamorphosis in the Goethean sense.

69 Through conceiving Euclidean and polar-Euclidean space in this manner it becomes clear that they are nothing else than the geometrical expression of the relationship between gravity and levity. 70 For gravity, through its field spreading outward from an inner centre, establishes a point-to-point relation between all things under its sway; 71 whereas levity draws all things within its domain into common plane-relations by establishing field-conditions wherein action takes place from the periphery towards the centre. 72 What distinguishes in both cases the plane at infinity from all other planes may be best described by calling it the all-embracing plane; correspondingly the point at infinity may be best described as the all-relating point.

73 In outer Nature the all-embracing plane is as much the 'centre' of the earth's field of levity as the all-relating point is the centre of Her field of gravity. 74 All actions of dynamic entities, such as that of the ur-plant and its subordinate types, start from this plane. 75 Seeds, eye-formations, etc., are nothing but individual all-relating points in respect of this plane. All that springs from such

points does so because of the point's relation to the all-embracing plane. 76 This may suffice to show how realistic are the mathematical concepts which we have here tried to build up.

77 When we set out earlier in this book in Chapter-8 to discover the source of Galileo's intuition, by which he had been enabled to find the theorem of the parallelogram of forces, 78 we were led to certain experiences through which all humans go in early childhood by erecting their body and learning to walk. 79 We were thereby led to realise that human's general capacity for thinking mathematically is the outcome of early experiences of this kind. 80 It is evident that geometrical concepts arising in human's mind in this way must be those of Euclidean geometry. For they are acquired by the will's struggle with gravity. 81 The dynamic law discovered in this way by Galileo was therefore bound to apply to the behaviour of mechanical forces-- that is, of forces acting from points outward.

82 In a similar way we can now seek to find the source of our capacity to form polar-Euclidean concepts. 83 As we were formerly led to experiences of human's early life on earth, so we are now led to your embryonic and even pre-embryonic existence. 84 Before human's super-sensible part enters into a physical body there is no means of conveying to it experiences other than those of levity, and this condition prevails right through embryonic development. 85 For while the body floats in the mother's foetal fluid it is virtually exempt from the influence of the earth's field of gravity.

86 History has given us a source of information from these early periods of human's existence in Traherne's recollections of the time when his soul was still in the state of cosmic consciousness. 87 Among his descriptions we may therefore expect to find a picture of levity-space which will confirm through immediate experience what we have arrived at along the lines of realistic mathematical reasoning. 88 Among poems quoted earlier, his *The Praeparative* and *My Spirit* do indeed convey this picture in the

clearest possible way. The following are relevant passages from these two poems.

89 In the first we read:

'Then was my Soul my only All to me,
A living endless Ey,
Scarce bounded with the Sky
Whose Power, and Act, and Essence was to see:
I was an inward Sphere of Light,
Or an interminable Orb of Sight,
Exceeding that which makes the Days . . .'

90 In the second poem the same experience is expressed in richer detail. There he says of his own soul that it -

... being Simple, like the Deity,
In its own Centre is a Sphere,
Not limited but everywhere.

It acts not from a Centre to
Its Object, as remote;
But present is, where it doth go
To view the Being it doth note
...

91 A strange extended Orb of Joy
Proceeding from within,
Which did on ev'ry side display
Its force; and being nigh of Kin
To God, did ev'ry way
Dilate its Self ev'n instantaneously,
Yet an Indivisible Centre stay,
In it surrounding all Eternity.
'Twas not a Sphere;
Yet did appear One infinite:
'Twas somewhat everywhere.'

92 Observe the distinct description of how the relation between circumference and centre is inverted by the former becoming itself an 'indivisible centre'. 93 In a space of this kind there is no Here and There, as in Euclidean space, for the consciousness is always and immediately at one with the whole space. 94 Motion is thus quite different from what it is in Euclidean space. Traherne himself italicised the word 'instantaneous', so important did he find this fact. 95 The quality of instantaneousness-- equal from the physical point of view to a velocity of the value âˆ-- 96 will occupy us more closely as a characteristic of the realm of levity

when we come to discuss the apparent velocity of light in connexion with our optical studies. 97 By thus realising the source in human of the polar-Euclidean thought-forms, we see the discovery of projective geometry in a new light. 98 For it now assumes the significance of yet another historical symptom of the modern re-awakening of human's capacity to remember own prenatal existence.

99 We know from our previous studies that the concept of polarity is not exhausted by conceiving the world as being constituted by polarities of one order only. 100 Besides primary polarities, there are secondary ones, the outcome of interaction between the primary poles. 101 Having conceived of Point and Plane as a geometrical polarity of the first order, we have therefore to ask what formative elements there are in geometry which represent the corresponding polarity of the second order. 102 The following considerations will show that these are the radius, which arises from the point becoming related to the plane, 103 and the spherically bent surface (for which we have no other name than that again of the sphere), arising from the plane becoming related to the point.

104 In Euclidean geometry the sphere is defined as 'the locus of all points which are equidistant from a given point'. 105 To define the sphere in this way is in accord with our post-natal, gravity-bound consciousness. 106 For in this state our mind can do no more than envisage the surface of the sphere point by point from its centre and recognise the equal distance of all these points from the centre. 107 Seen thus, the sphere arises as the sum-total of the end-points of all the straight lines of equal length which emerge from the centre-point in all directions. 108 Fig. 8 indicates this schematically. Here the radius, a straight line, is clearly the determining factor.

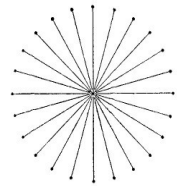

FIG. 8.

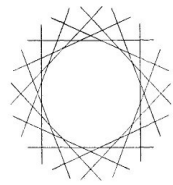

FIG. 9.

109 We now move to the other pole of the primary polarity, that is to the plane, and let the sphere arise by imagining the plane

approaching an infinitely distant point evenly from all sides. 110 We view the process realistically only by imagining ourselves in the plane, so that we surround the point from all sides, with the distance between us and the point diminishing gradually. 111 Since we remain all the time on the surface, we have no reason to conceive any change in its original position; that is, we continue to think of it as an all-embracing plane with regard to the chosen point.

112 The only way of representing the sphere diagrammatically, as a unit bearing in itself the character of the plane whence it sprang, is as shown in Fig. 9 above, 113 where a number of planes, functioning as tangential planes, are so related that together they form a surface which possesses everywhere the same distance from the all-relating point.

114 Since Point and Plane represent in the realm of geometrical concepts what in outer Nature we find in the form of the gravity-levity polarity, 115 we may expect to meet Radius and Sphere as actual formative elements in Nature, wherever gravity and levity interact in one way or another. 116 A few observations may suffice to give the necessary evidence. Further confirmation will be furnished by the ensuing chapters.

117 The Radius-Sphere antithesis appears most obviously in the human body, the radial element being represented by the limbs, the spherical by the skull. 118 The limbs thus become the hieroglyph of a dynamic directed from the Point to the Plane, and the skull of the opposite. 119 This indeed is in accord with the distribution in the organism of the sulphur-salt polarity, as we learn't from our physiological and psychological studies. 120 Inner processes and outer form thus reveal the same distribution of poles.

121 In the plant the same polarity appears in stalk and leaf. Obviously the stalk represents the radial pole. 122 The connexion between leaf and sphere is not so clear: in order to recognise it we must appreciate that the single plant is not a self-contained entity to the same degree as is the human being. 123 The equivalent of the

single human is the entire vegetable covering of the earth. In human there is an individual centre round which the bones of your skull are curved; in the plant world the equivalent is the centre of the earth. 124 It is in relation to this that we must conceive of the single leaves as parts of a greater sphere.

125 In the plant, just as in human, the morphological polarity coincides with the biological. 126 There is, on the one hand, the process of assimilation (photosynthesis), so characteristic of the leaf. 127 Through this process matter passes over from the aeriform condition into that of numerous separate, characteristically structured solid bodies-- the starch grains. 128 Besides this kind of assimilation we have learn't to recognise a higher form which we called 'spiritual assimilation'. 129 Here, a transition of substance from the domain of levity to that of gravity takes place even more strikingly than in ordinary (physical) assimilation (Chapter -10).

130 The corresponding process in the linear stalk is one which we may call 'sublimation'-- again with its extension into 'spiritual sublimation'. 131 Through this process matter is carried in the upward direction towards ever less ponderable conditions, and finally into the formless state of pure 'chaos'. 132 By this means the seed is prepared (as we have seen) with the help of the fire-bearing pollen, so that after it has fallen to the ground, it may serve as an all-relating point to which the plant's Type can direct its activity from the universal circumference.

133 In order to find the corresponding morphological polarity in the animal kingdom, we must realise that the animal, by having the main axis of its body in the horizontal direction, has a relationship to the gravity-levity fields of the earth different from those of both human and plant. 134 As a result, the single animal body shows the sphere-radius polarity much less sharply. 135 If we compare the different groups of the animal kingdom, however, we find that the animals, too, bear this polarity as a formative element. 136 The birds represent the spherical (dry, saline) pole; the

ruminants the linear (moist, sulphurous) pole. The carnivorous quadrupeds form the intermediary (mercurial) group. 137 As ur-phenomenal types we may name among the birds the eagle, clothed in its dry, silicic plumage, hovering with far-spread wings in the heights of the atmosphere, united with the expanses of space through its far-reaching sight; 138 among the ruminants, the cow, lying heavily on the ground of the earth, given over entirely to the immensely elaborated sulphurous process of its own digestion. 139 Between them comes the lion-- the most characteristic animal for the preponderance of heart-and-lung activities in the body, with all the attributes resulting from that.

140 Within the scope of this book it can only be intimated briefly, but should not be left unmentioned for the sake of those interested in a further pursuit of these lines of thought, 141 that the morphological mean between radius and sphere (corresponding to Mercurius in the alchemical triad) is represented by a geometrical figure known as the 'lemniscate', a particular modification of the so-called Cassinian curves.

RADIANT MATTER

Ernst Lehrs

13 When human in the state of world-onlooker undertook to form a dynamic picture of the nature of matter, it was inevitable that of all the qualities which belong to its existence you should be able to envisage only those pertaining to gravity and electricity. 2 Because human consciousness, at this stage of its evolution, was closely bound up with the force of gravity inherent in the human body, you was unable to form any conception of levity as a force opposite to gravity. 3 Yet, Nature is built bipolarically, and polarity-concepts are therefore indispensable for developing a true understanding of Her actions. 4 This accounts for the fact that the unipolar concept of gravity had eventually to be supplemented by some kind of bipolar concept.

5 Now, the only sphere of Nature-phenomena with a bipolar character accessible to the

onlooker-consciousness 'was that of electricity. 6 It was thus that human in this state of consciousness was compelled to picture the foundation of the physical universe as being made up of gravity and electricity, 7 as we meet them in the modern picture of the atom, with its heavy electro-positive nucleus and the virtually weightless electro-negative electrons moving round it.

8 Once scientific observation and thought are freed from the limitations of the onlooker-consciousness, both gravity and electricity appear in a new perspective, though the change is different for each of them. 9 Gravity, while it becomes one pole of a polarity, with levity as the opposite pole, still retains its character as a fundamental force of the physical universe, the gravity-levity polarity being one of the first order. Not so electricity. 10 For, as the following discussion will show, the electrical polarity is one of the second order; moreover, instead of constituting matter as is usually believed, electricity turns out to be in reality a product of matter.

11 We follow Goethe's line when, in order to answer the question, 'What is electricity?' we first ask, 'How does electricity arise?' 12 Instead of starting with phenomena produced by electricity when it is already in action, and deriving from them a hypothetical picture, we begin by observing the processes to which electricity owes its appearance. 13 Since there is significance in the historical order in which facts of Nature have come to human's knowledge in the past, 14 we choose as our starting-point, among the various modes of generating electricity, the one through which the existence of an electric force first became known. 15 This is the rousing of the electric state in a body by rubbing it with another body of different material composition. Originally, amber was rubbed with wool or fur.

16 By picturing this process in our mind we become aware of a certain kinship of electricity with fire, since for ages the only known way of kindling fire was through friction. 17 We notice that in both

cases human had to resort to the will-power invested in own limbs for setting in motion two pieces of matter, 18 so that, by overcoming their resistance to this motion, you released from them a certain force which you could utilise as a supplement to your own will. 19 The similarity of the two processes may be taken as a sign that heat and electricity are related to each other in a certain way, the one being in some sense a metamorphosis of the other. 20 Our first task, therefore, will be to try to understand how it is that friction causes heat to appear in manifest form.

21 There is no friction unless the surfaces of the rubbed bodies have a structure that is in some way interfered with by the rubbing, while at the same time they offer a certain resistance to the disturbance. 22 This resistance is due to a characteristic of matter, commonly called cohesion. 23 Now we know that the inner coherence of a physical body is due to its point-relationship, that is to the gravitational force bound up with it. 24 Indeed, cohesion increases as we pass from the gaseous, through the liquid, to the solid state of matter.

25 Whilst a body's cohesion is due to gravity, its spatial extendedness is, as we have seen, due to levity. 26 If we reduce the volume of a piece of physical matter by means of pressure, we therefore release levity-forces previously bound up in it, and these, as always happens in such cases, appear in the form of free heat. 27 Figuratively speaking, we may say that by applying pressure to matter, latent levity is pressed out of it, somewhat like water out of a wet sponge.

28 The generation of free heat by friction rests on quite similar grounds. Obviously, friction always requires a certain pressure. 29 This alone, however, would not account for the amount of heat easily produced by friction. To the pressure there is in this case added a certain measure of encroachment upon the unity of the material substance. 30 In the case of friction between two solid bodies, this may go so far that particles of matter are completely detached from the cohesive whole. 31 The result is an increase in the number of single

mass-centres on the earth, as against the all-embracing cosmic periphery. 32 This diminishes the hold of levity on the total amount of physical matter present on the earth. 33 Again, the levity thus becoming free appears as external heat. (In the reverse case when, for instance through melting, a number of single physical bodies become one, free heat becomes latent.)

34 Both the diminishing of spatial extension and the breaking up of a whole into parts entail an increase in the quality 'dry'. 35 This applies not only in the sense that the parts which have become independent units are 'dry' in relation to each other-- formerly coherent matter being turned into dust-- 36 but also in the other sense, and one valid in both cases, that levity and gravity are losing part of their previous inter-connexion. 37 If this twofold process of 'becoming dry' reaches a certain intensity, the substances concerned, provided they are inflammable, begin to burn, with the result that dry heat escapes and dry ash is formed. 38 We note that in each case we are dealing with a change in the relationship between the poles of a polarity of the first order.

39 We will now apply this picture of the process of friction to the instance when, as a result of this action, electricity appears.

40 Originally the evoking of the electric condition was ascribed solely to the nature of amber, the only substance known to possess this property. 41 To-day we know that not the amber alone, but its coming together with another substance of different nature, in this instance an animal substance of the nature of hair or silk, is required. 42 Whatever substances we use for friction, they must always be different in nature, so as to allow both kinds of electricity to appear at once. 43 Which of the two kinds imposes its presence the more strongly upon the observer depends on purely extraneous conditions which have nothing to do with the process itself.

44 Obviously, if we wish to understand the qualitative difference between the two kinds of electricity, we must investigate the qualitative difference in the material substances, which give rise to electricity when they are

rubbed together. 45 We shall again follow the historical line by examining the two substances which first taught human the polar nature of electricity. 46 They are glass and resin, after which, as we mentioned, the two electricities were even named in the beginning. 47 Our functional conception of matter, developed earlier (Chapter-11), allows us to recognise in these two substances representatives of the Salt-Sulphur polarity. 48 Indeed, glass as a mineral substance, which actually owes its specific character to the presence of silicon in it, clearly stands on the phosphoric-crystalline side, while resin, being itself a sort of 'gum', on the sulphurous-volcanic side. 49 In fact, sulphur itself was soon found to be a particularly suitable substance for producing 'resin'-electricity.

50 Now the usual way of producing one kind of electricity is by rubbing resin (or sulphur, or ebonite) with wool or fur, and the other by rubbing glass with leather. 51 At first sight, it does not seem as if the two counter-substances represent the required alchemic counter-poles to resin and glass. For both hair and leather are animal products and therefore seem to be of like nature. 52 Closer inspection, however, shows that they do obey the rule. For hair, like all horny substances, is a dead product of external secretion by the animal organism. 53 An ur-phenomenal example of it, showing its kinship to glass-like substances, is the transparent cornea of the eye, close to the crystal-lens. 54 Leather, on the other hand, is a product of the hypodermic part of the body and, as such, belongs to those parts of the organism which are filled with blood, and, therefore, permeated with life. 55 Note as a characteristic of leather that it requires a special treatment, tanning, to make it as immune from decay as hair is by nature. 56 Hair and leather, therefore, represent in themselves a salt-sulphur polarity, and thus fulfill the corresponding function when brought together with resin or glass respectively.

57 What is true for the particular substances which originally led human to discover the dual nature of electricity, holds good equally

for any pair of substances capable of assuming the electric state when rubbed against each other. 58 If we examine from this point of view the series of such substances, as usually given in the textbooks on electricity, 59 we shall always find a substance of extreme salt-character at the one end, and one of extreme sulphur-character at the other, the substances as a whole forming a gradual transition from one extreme to the other. 60 Which kind of electricity appears on each, when submitted to friction, depends on whether the counter-substance stands on its right or left, in the series. 61 It is the particular relation between the two which makes them behave in one way or the other.

62 There are cases which seem to elude this law, and investigation has shown that other characteristics of the rubbed bodies, such as surface quality, can have a modifying influence. 63 For lack of a guiding idea they are treated in the textbooks as 'irregularities'. Observation led by a true polarity concept shows that in these cases also the rule is not violated. 64 In this respect, interesting information can be gained from the observations of J. W. Ritter (1776-1810), an ingenious Naturphilosoph from the circle round Goethe, 65 but to whom, also, physical science is indebted for his discovery of the ultra-violet part of the spectrum and of galvanic polarisation. 66 Among his writings there is a treatise on electricity, giving many generally unknown instances of frictional electricity which are in good accord with our picture and well worth investigating. 67 According to Ritter, even two crystalline substances of different hardness, such as Calcite and quartz, become electric when rubbed together, the softer playing the part of 'resin' and the harder that of 'glass'.

68 These few facts connected with the generation of frictional electricity are enough to allow us to form a picture of the nature of the polarity represented by the two kinds of electricity.

69 We remember that in the case of the generation of heat through friction, as a result of an encroachment upon the cohesion of the material body involved, 70

the relationship between levity and gravity in it changes from 'moist' to 'dry' and that the effect of this is the appearance of 'fire' and 'dust' as poles of a primary polarity. 71 This process, however, is altered when the bodies subjected to friction are opposed to each other in the sense of a salt-sulphur polarity. 72 The effect then is that the liberated levity, under the influence of the peculiar tension between the two bodies, remains bound in the realm of substance and becomes itself split up polarically.

73 Clearly, then, in the case of electrical polarity we encounter a certain form of gravity-bound levity, and this in a twofold way. 74 Owing to the contrasting nature of the two bodies involved in the process, the coupling of gravity and levity is a polar one on both sides. 75 The electrical polarity thus turns out to be itself of the nature of a secondary polarity.

76 Two more recently discovered means of evoking the electric condition in a piece of matter confirm this picture. They are the so-called piezo-electricity and pyro-electricity. 77 Both signify the occurrence of the electrical polarity at the two ends of an asymmetrically built (hemimorphous) crystal, as the result of changing the crystal's spatial condition. 78 In piezo-electricity the change consists in a diminution of the crystal's volume through pressure; in pyro-electricity, in an increase of the crystal volume by raising its temperature. 79 The asymmetry of the crystal, due to a one-sided working of the forces of crystallisation, plays the same role here as does the alchemic opposition between the two bodies used for the production of frictional electricity.

80 It is typical of the scientist of the past that he was dependent on phenomena brought about by a highly developed experimental technique for becoming aware of certain properties of the electrical force, 81 whereas for the realistic observer these properties are revealed at once by the most primitive electric phenomena. 82 We remember Eddington's description of the positron as 'negative material', and his subsequent remarks, which show

the paradoxical nature of this concept if applied to the hypothetical interior of the atom (Chapter-4). 83 The quite primitive phenomenon of electrical repulsion and attraction shows us the same thing in a manner of which it is not difficult to form a conception.

84 Modern physics itself, with the help of Faraday's field-concept, describes these phenomena as caused by pressure-- resulting from the meeting in space of two similar electrical fields-- and suction-- resulting from the meeting of two dissimilar fields. 85 In the first case the space between the two electrically charged bodies assumes a degree of density, as if it were filled with some elastic material. 86 In the second instance the density of the space where the two fields intermingle is lower than that of its surroundings. 87 Here, clearly, we have a state of negative density which acts on the electrically charged bodies just as a lowering of pressure acts on a gas: 88 in both cases movement occurs in the direction leading from the higher to the lower density. 89 Electricity thus shows itself capable of producing both gravity and levity effects, thereby once more confirming our picture of it.

90 Our next task will be to examine the galvanic form of generating electricity, in order to gain further light on our picture of the electrical polarity.

91 Galvanism, as it became established through Volta's work, rests on certain properties of the metallic substances of the earth. 92 Compared with the substances which may be used for producing electricity through friction, the metals hold a mid-position. 93 They are all essentially mercurial substances.-- In quicksilver, which for this reason was given the name 'mercury' by the alchemists, this fact comes to an ur-phenomenal appearance. 94 Among the many facts proving the mercurial nature of the metals, there is one of particular interest to us. This is their peculiar relationship to the processes of oxidation and reduction.

95 Metals, in their metallic state, are bearers of latent levity, which can be set free either through combustion or through corrosion.

96 They differ from one another by their relative degree of eagerness to enter into and remain in the metallic, 97 that is, the reduced state, or to assume and keep the state of the oxide (in which form they are found in the various metallic oxides and salts). 98 There are metals such as gold, silver, etc., for which the reduced state is more or less natural; others, such as potassium, sodium, etc., find the oxidised state natural and can be brought into and kept in the reduced state only by artificial means. 99 Between these extremes there are all possible degrees of transition, some metals more nearly resembling the 'noble', others more nearly the 'corrosive', metals.

100 We remember that it was the different relationship of sulphur and phosphorus to reduction and oxidation which led us to envisage them as ur-phenomenal representatives of the alchemic polarity. 101 We may therefore say that there are metals which from the alchemic point of view more nearly resemble sulphur, others more nearly phosphorus, whilst others again hold an intermediary position between the extremes. 102 It is on these differences among the various metals that their galvanic properties are based.

103 Let us from this point of view contemplate the following series of chemical elements, which is a representation of the so-called voltaic series:

104 Graphite, Platinum, Gold, Silver, Copper, Iron, Tin, Lead, Zinc, Aluminium, Magnesium, Sodium, Potassium. Any two of these metals constitute a voltaic cell. 105 Its electromotive force is determined by the distance in the series between the metals used. 106 Just as in the case of frictional electricity, the kind of electricity which is supplied by a certain metal depends on whether the other metal with which it is coupled stands to the right or to the left of it in the series.

107 Let us now see what happens in a galvanic cell when the two different metals are simultaneously exposed to the chemical action of the connecting fluid. 108 Each metal by itself would undergo oxidation with greater or less intensity, and the calorific energy hidden in it would become free in

the form of heat. 109 This process suffers a certain alteration through the presence of the second metal, which sets up an alchemic tension between the two. 110 Instead of a proper segregation of the primary polarity, heat-dust (in this case, heat-oxide), the heat remains matter-bound and appears on the surface of the two metals in a secondarily split form as positive and negative electricity.

111 The similarity between this process and the frictional generation of electricity is evident.

112 Our observations have shown that the emergence of the electric state, whether it be caused by friction or galvanically, depends on matter entering into a condition in which its cohesion is loosened-- 113 or, as we also put it, on its being turned into 'dust'-- and this in such a way that the escaping levity remains dust-bound. 114 This picture of electricity now enables us to give a realistic interpretation of certain phenomena which, 115 in the interpretation which the physicist of the past was bound to give them, have contributed much to the tightening of the net of scientific illusion. 116 Some sixty years after Dalton had established, purely hypothetically, the theory of the atomistic structure of matter, scientific research was led to the observation of actual atomistic phenomena. 117 Crookes found electricity appearing in his tubes in the form of discrete particles, with properties hitherto known only as appertaining to mass. 118 What could be more natural than to take this as evidence that the method of thought developed during the past era of science was on the right course?

119 The same phenomena appear in quite a different light when we view them against the background of the picture of electricity to which our observations have led. 120 Knowing that the appearance of electricity depends on a process of atomisation of some sort, we shall expect that where electricity becomes freely observable, it will yield phenomena of an atomistic kind. 121 The observations of electricity in a vacuum, therefore, yield no confirmation whatsoever of the atomistic view of matter.

122 The same is true of the phenomena bound up with radioactivity, which were discovered in direct consequence of Crookes's work. 123 We know that the naturally radioactive elements are all in the group of those with the highest atomic weight. 124 This fact, seen together with the characteristics of radioactivity, tells us that in such elements gravity has so far got the upper hand of levity that the physical substance is unable to persist as a spatially extended, coherent unit. 125 It therefore falls asunder, with the liberated levity drawn into the process of dispersion. Seen thus, radioactivity becomes a symptom of the earth's old age.

126 Before entering into a discussion of the question, which naturally arises at this point, as to how levity and gravity by their two possible ways of interaction--'sulphurous' or 'saline'-- determine the properties of so-called positive and negative electricity, 127 we shall first study the third mode of generating electricity, namely, by electromagnetic induction. 128 Along this way we shall arrive at a picture of the magnetic force which corresponds to the one already obtained of electricity. 129 This will then lead us to a joint study of the nature of electric polarity and magnetic polarity.

130 The discovery of the phenomena we call electromagnetic depended on the possibility of producing continuous electrical processes. This arose with Volta's invention. 131 When it became necessary to find a concept for the process which takes place in an electric conductor between the poles of a galvanic cell, the concept of the 'current', borrowed from hydrodynamics, suggested itself. 132 Ever since then it has been the rule to speak of the existence of a current within an electric circuit; its strength or intensity is measured in terms of a unit named in honour of Ampere.

133 This concept of the current has had a fate typical of the whole relation of human thought to the facts connected with electricity. 134 Long after it had been coined to cover phenomena which in themselves betray no movement of any kind between the electrical

poles, other phenomena which do in fact show such movements became known through Crookes's observations. 135 Just as in the case of atomism, they seemed to prove the validity of the preconceived idea of the current. 136 Soon, however, radiant electricity showed properties which contradicted the picture of something flowing from one pole to the other. 137 The cathode rays, for instance, were found to shoot forth into space perpendicularly from the surface of the cathode, without regard to the position of the anode. 138 At the same time Maxwell's hydrodynamic analogy (as our historical survey has shown) led to a view of the nature of electricity by which this very analogy was put out of court. 139 By predicting certain properties of electricity which come to the fore when its poles alternate rapidly, he seemed to bring electricity into close kinship with light. 140 Mathematical treatment then made it necessary to regard the essential energy process as occurring, not from one pole to the other, but at right angles to a line joining the poles (Poynting's vector). 141 This picture, however, satisfactory though it was in the realm of high frequency, failed as a means of describing so-called direct-current processes.

142 As a result of all this the theory of electricity has fallen apart into several conceptual realms lying, as it were, alongside one another, each consistent in itself but lacking any logical connexion with the others. 143 Although the old concept of the electric current has long lost its validity, scientific thought (not to speak of the layman's) has not managed to discard it. 144 To do this must therefore be our first task, if we want to attain to a realistic picture of electromagnetism.

145 While keeping strictly to the historical order of things, we shall try first to form a picture of what happens when we connect two electrically charged bodies by a conductor. 146 We know that we rightly describe the change of the dynamic properties of the part of space, in which the two bodies are present, by saying that a certain electric field prevails in it. 147 This field possesses different 'potentials' at its various points and

so there exists a certain potential difference between the two electric charges. What then happens when a so-called 'conductor' is brought into such a field?

148 From the point of view of the field-concept, conductivity consists in the property of a body not to allow any change of potential along its surface. 149 Such a surface, therefore, is always an equipotential. In the language of alchemy, conductivity is a mercurial property. In the presence of such a body, therefore, no Salt-Sulphur contrasts can obtain. 150 In view of what we found above as the mean position of the metals in the alchemic triad, it is significant that they, precisely, should play so outstanding a role as electrical conductors.

151 If we keep to pure observation, the only statement we can make concerning the effect produced by the introduction of such a body into the electric field is that this field suddenly disappears. 152 We shall see later in which direction this vanishing occurs. For the present it is sufficient to have formed the picture of the disappearance of the electrical condition of space as a result of the presence of a body with certain mercurial properties.

153 Nothing else, indeed, happens when we make the process continuous by using a galvanic source of electricity. 154 All that distinguishes a galvanic cell from the sources of electricity used before the time of Volta is its faculty of immediately re-establishing the field which prevails between its poles, whenever this field becomes extinguished by the presence of a conductor. 155 Volta himself saw this quite correctly. In his first account of the new apparatus he describes it as 'Leyden jars with a continuously re-established charge'. 156 Every enduring electrical process, indeed, consists in nothing but a vanishing and re-establishment of the electrical field with such rapidity that the whole process appears continuous.

157 Here, also, pure observation of the effect of a conductor in an electric field tells us that its action consists in the annihilation of the field. 158 There is no phenomenon which allows us to state that this process takes place along the axis

of the conductor. 159 If we wish to obtain a picture of the true direction, we must consider the condition of space which arises in place of the electric condition that has disappeared.

160 With the possibility of turning the cancellation of the electrical condition of space into a continuous process, it became possible to observe that the neutralisation of electric charges entails the appearance of heat and magnetism. 161 We must now ask which are the qualities of electricity on the one hand, and of heat and magnetism on the other, which account for the fact that where electricity disappears, the two latter forces are bound to appear. 162 Since magnetism is the still unknown entity among the three, we must now deal with it.

163 Unlike electricity, magnetism was first known in the form of its natural occurrence, namely as a property of certain minerals. 164 If we follow the same course which led us to start our study of electricity with the primitive process of generating it, we shall turn now to the basic phenomenon produced by a magnetic field already in existence. 165 Only when we have learn't all we can from this, shall we proceed to ask how magnetism comes into being. Obviously, we shall find this basic phenomenon in the effect of a magnet on a heap of iron filings.

166 Let us, to begin with, compare a mass of solid iron with the same quantity of it in powdered form. The difference is that the powder lacks the binding force which holds the solid piece together. 167 Now let us expose the powdered iron to the influence of a magnet. At once a certain ordering principle takes hold of the single particles. 168 They no longer lie at random and unrelated, apart from the inconspicuous gravitational effect they exert on one another, but are drawn into a coherent whole, thus acquiring properties resembling those of an ordinary piece of solid matter.

169 Read thus, the phenomenon tells us that a part of space occupied by a magnetic field has qualities which are otherwise found only where a coherent solid mass is present. 170 A magnetic piece of solid iron, therefore, differs from a non-magnetic piece

by giving rise in its surroundings to dynamic conditions which would otherwise exist only in its interior. 171 This picture of the relatedness of magnetism to solidity is confirmed by the fact that both are cancelled by heat, and increased by cold.

172 By its magnetic properties iron thus reveals itself as a substance capable of assuming the condition of solid matter to a degree surpassing ordinary solidity. 173 As an exceptional kind of metal it forms the counter-pole to mercury, in which the solid-fluid condition characteristic of all metallic matter is as much shifted towards the fluid as in iron it is to the solid. 174 Note in this respect the peculiar resistance of iron to the liquefying effect which mercury has on the other metals.

175 This picture of magnetism enables us to understand at once why it must occur together with heat at the place where an electric polarity has been cancelled by the presence of a conductor. 176 We have seen that electricity is levity coupled in a peculiar way with gravity; it is polarised levity (accompanied by a corresponding polarisation of gravity). 177 An electric field, therefore, always has both qualities, those of levity and of gravity. 178 We saw a symptom of this in electrical attraction and repulsion, so called; the attraction, we found, was due to negative density, the repulsion to positive density, imparted to space by the electrical fields present there. 179 Now we see that when, through the presence of a conductor, the electrical field round the two opposing poles vanishes, in its place two other fields, a thermal and a magnetic, appear. 180 Clearly, one of them represents the levity-part, the other the gravity-part, of the vanished electric field. 181 The whole process reminds one of combustion through which the ponderable and imponderable parts, combined in the combustible substance, fall apart and appear on the one hand as heat, and on the other as oxidized substance ('ash'). 182 Yet, between these two manifestations of heat there is an essential qualitative difference.

183 Although, from our view-point, magnetism represents only one 'half of a phenomenon, the other half of which is heat, we must not

forget that it is itself a bipolar force. 184 Thus, despite its apparent relation to gravity it does not represent, as gravity does, one pole of a primary polarity, with heat as the other pole. 185 Rather must it carry certain qualities of levity which, together with those of gravity, appear in a polarically opposite manner at its two poles. 186 Details of this will be shown later when we come to investigate the individual qualities of the two poles of magnetism and electricity. 187 Hence the heat that forms the counterpart to magnetism cannot be pure levity either. As the result of a certain coupling with gravity, it too has somehow remained polarically split.

188 This can easily be seen by considering the following. Unlike the levity-gravity polarity, in which one pole is peripheral and the other point-centred, both Doles of the electrical polarity are point-centred; 189 both are located in physical space, and thereby determine a definite direction within this space. It is this direction which remains a characteristic of both the magnetic and the thermal fields. 190 The direction of the thermal field as much as that of the magnetic is determined by its having as its axis the conductor joining the poles of the antecedent electrical field. 191 Both fields supplement each other in that the thermal radiation forms the radii which belong to the circular magnetic lines-of-force surrounding the conductor.

192 Our picture of the process which is commonly called an electric current is now sufficiently complete to allow us to make a positive statement concerning the direction in which it takes place. 193 Let us once more sum up: In order that this process may occur, there must be present in an electrically excited part of space a body which does not suffer the particular polarisation of space bound up with such a field. 194 As a result, the electrical field disappears, and in place of it appear a thermal field and a magnetic field, both having as their axis the line connecting the two poles. 195 Each of them spreads out in a direction at right angles to this fine. Obviously, therefore, it is in this radial direction that the transformation of

the electrical into the thermo-magnetic condition of space must take place.

196 This picture of the electro-thermo-magnetic happening, as regards its direction, is in complete accord with the result obtained (as indicated earlier) by the mathematical treatment of high-frequency phenomena. 197 Once more we see that quite primitive observations, when properly read, lead to findings for which scientific thought had to wait until they were forced on it by the progress of experimental technique-- 198 as even then science was left without a uniformly valid picture of the dynamic behaviour of electricity.

199 Further, we can now see that when we apply electricity to practical purposes, we are in fact seldom using electricity itself, but other forces 200 that is, other combinations of gravity and levity which we make effective by making electricity disappear. 201 The same is true of most of the methods of measuring electricity. As a rule, the force which sets the instrument in motion is not electricity but another force (magnetism, heat, etc.) which appears in the place of the vanishing electricity. 202 Thus the so-called intensity of an electric current is actually the intensity with which the electricity in question disappears! 203 Electricity serves us in our machines in the same way that food serves a living organism: it gets itself digested, and what matters is the resulting secondary product.

204 Just as alterations in the electrical condition of space give rise to the appearance of a magnetic field, any alteration of the magnetic state of space gives rise to the appearance of an electrical field. This process is called electromagnetic induction. 205 With its discovery, the generation of electricity through friction and in the galvanic way was supplemented by a third way. 206 By this means the practical use of electricity on a large scale became possible for the first time. 207 If our picture of the two earlier processes of generating electricity is correct, then this third way must also fit into the picture, although in this case we have no longer to do

with any direct atomisation of physical matter. 208 Our picture of magnetism will indeed enable us to recognise in electromagnetic induction the same principle on which we found the two other processes to rest.

209 Magnetism is polarised gravity. Hence it has the same characteristic of tending always to maintain an existent condition. 210 In bodies subject to gravity, this tendency reveals itself as their inertia. It is the inertia inherent in magnetism which we employ when using it to generate electricity. 211 The simplest example is when, by interrupting a 'primary current', we induce a 'secondary current' in a neighbouring circuit. 212 By the sudden alteration of the electric condition on the primary side, the magnetic condition of the surrounding space is exposed to a sudden corresponding change. 213 Against this the magnetic field 'puts up' a resistance by calling forth, on the secondary side, an electrical process of such direction and strength that the entire magnetic condition remains first unaltered and then, 214 instead of changing suddenly, undergoes a gradual transformation which ideally needs an infinite time for its accomplishment (asymptotic course of the exponential curve). 215 This principle rules every process of electromagnetic induction, whatever the cause and direction of the change of the magnetic field.

216 We know that electromagnetic induction takes place also when a conductor is moved across a magnetic field in such a way that, as the technical term goes, it 'cuts' the field's lines of force. 217 Whereas the process discussed above is employed in the transformer, this latter process is used in generation of electricity by dynamo. 218 We have seen that a magnetic field imparts to the relevant part of space qualities of density which otherwise prevail only in the interior of solid masses. 219 We remember further that the appearance of electricity, in the two other modes of generating it, is caused by the loosening of the coherence of the material substance. 220 A similar loosening of the coherence of the magnetic field takes place when its field-

lines are cut by the movement of the conductor across it. 221 Just as heat occurs when we move a solid object through a liquid, electricity occurs when we move a conductor across a magnetic field. In each case we interfere with an existing levity-gravity relationship.

222 Having established thus far the picture of both electricity and magnetism which shows each as an outcome of certain levity-gravity interactions, 223 we now ask how, in particular, negative and positive electricity on the one hand and north and south magnetism on the other are determined by these interactions. Let us again begin with electricity.

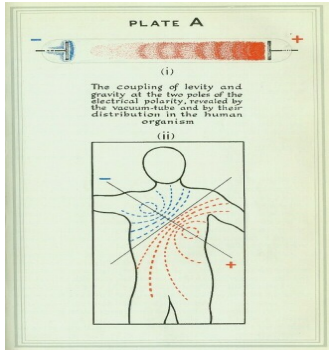
224 We remember that Galvani was led to his observations by the results of Walsh's study of the electric fishes. 225 While Galvani clung to the view that in his own experiments the source of the electrical force lay within the animal bodies, Volta saw the fallacy of that. 226 He then conceived the idea of imitating with purely inorganic substances the set-up which Galvani had come upon by accident. 227 The paradoxical result-- as he himself noticed with surprise-- was that his apparatus turned out to be a close replica of the peculiar organ with which the electric fishes are endowed by Nature. We must now take a closer view of this organ.

228 The electric organ of such a fish consists of many thousands of little piles, each made up of a very great number of plates of two different kinds, arranged in alternating layers. 229 The two kinds differ in substance: in one case the plate is made from a material similar to that present in the nervous system of animals; 230 in the other the resemblance is to a substance present in the muscular system, though only when the muscles are in a state of decay. 231 In this way the two opposing systems of the animal body' seem to be brought here into direct contact, repeated many thousands of times.

232 In the electric fishes, accordingly, sensation and will are brought into a peculiar interrelation. 233 For the will-pole is related to its bodily foundation in a manner which otherwise obtains only between the nervous system and the psychological

processes co-ordinated with it. 234 These fishes then have the capacity to send out force-currents which produce in other animals and in human 'concussion of the limbs', or in extreme cases paralysis and even death. 235 Through describing the process in this way we realise that electricity appears here as metamorphosed animal will, which takes this peculiar form because part of the animal's volitional system is assimilated to its sensory system in an exceptional manner.

236 It is known to-day that what Nature reveals so strikingly in the case of the electric fish, is nothing but the manifestation of a principle at work in the bodies of all beings endowed with sensation and volition-- 237 in corporeal terms, with the duality of a nervous and a muscular system - and therefore at work also in the human body. 238 Observation has shown that the activities of these two systems in human and animal are accompanied by the occurrence of different electric potentials in different parts of the body. 239 Plate A, Fig. iii, shows the distribution of the two polar electric forces in the human body. The bent lines in the diagram stand for curves of equal electric potential.



240 The straight line between them is the neutral zone. As might be expected, this line runs through the heart. What seems less obvious is its slanting position. Here the asymmetry, characteristic of the human body, comes to expression.

241 If we remember that the nervous system represents the salt-pole, and the metabolic system the sulphur-pole, of the human organism, and if we take into account the relationship between levity and gravity at the two poles, 242 we can see from the distribution of the two electricities that the coupling of levity and gravity at the negative pole of the electrical polarity is such that levity descends into gravity, while

at the positive pole gravity rises into levity. 243 Negative electricity therefore must have somehow a 'spherical' character, and positive electricity a 'radial'.

244 This finding is fully confirmed by electrical phenomena in the realm of Nature most remote from human-- though it was an effort to solve the enigma of human which led to the discovery of this realm. 245 Since Crookes's observations of the behaviour of electricity in a vacuum it is common knowledge that only the negative kind of electricity occurs as a freely radiating force-- though it retains some properties of inertia,-- 246 whereas positive electricity seems to be much more closely bound to minute particles of ponderable matter. 247 Here again we find gravity-laden levity on the negative side, levity-raised gravity on the positive.

248 The same language is spoken by the forms in which the luminous phenomena appear at the two poles of a Crookes tube. 249 Fig. i on Plate A represents the whole phenomenon as far as such a diagram allows. Here we see on the positive side radial forms appear, on the negative side planar-spherical forms. 250 As symbols of Nature's script, these forms tell us that cosmic periphery and earthly centre stand in a polar relation to each other at the two ends of the tube. 251 Our optical studies will later show that the colours which appear at the anode and cathode are also in complete accord with this.

252 At this point in our discussion it is possible to raise, without risk of confusing the issue, the question of the distribution of the two electric forces over the pairs of substances concerned in the generation of electricity both by friction and in the galvanic way. 253 This distribution seems to contradict the picture to which the foregoing observations have led us, for in both instances the 'sulphurous' substances (resin in one, the nobler metals in the other) become bearers of negative electricity; 254 while the 'saline' substances (glass and the corrosive metals) carry positive electricity. 255 Such a criss-crossing of the poles-surprising as it seems at first sight-- is not new to us. 256 We have met it in the distribution of

function of the plant's organs of propagation, and we shall meet a further instance of it when studying the function of the human eye. 257 Future investigation will have to find the principle common to all instances in Nature where such an interchange of the poles prevails.

258 While the electric field arising round an electrified piece of matter does not allow any recognition of the absolute characteristics of the two opposing electrical forces, we do find them revealed by the distribution of electricity in the human body. 259 Something similar holds good for magnetism. Only, to find the phenomena from which to read the absolute characteristics of the two sides of the magnetic polarity, we must not turn to the body of human but to that of the earth, 260 one of whose characteristics it is to be as much the bearer of a magnetic field as of gravitational and levitational fields. 261 There is significance in the fact that even to-day, when the tendency prevails to look for causes of natural phenomena not in the macrocosmic expanse, but in the microscopic confines of space, the two poles of magnetism are named after the magnetic poles of the earth. 262 It indicates the degree to which human's feeling instinctively relates magnetism to the earth as a whole.

263 In our newly developed terminology we may say that magnetism, as a polarity of the second order, represents a field of force both of whose poles are situated within finite space, 264 and that in the macro-telluric mother-field this situation is such that the axis of this field coincides more or less with the axis of the earth's physical body. 265 Thus the magnetic polarisation of the earth as a letter in Nature's script bids us rank it alongside other phenomena which in their way are an expression of the earth's being polarised in the north-south direction.

266 The Austrian geographer, E. Suess, in his great work The Countenance of the Earth, first drew attention to the fact that an observer approaching the earth from outer space would be struck by the one-sided distribution and formation of the earth's continents. 267 He would notice that most of

the dry land is in the northern hemisphere, leaving the southern hemisphere covered mainly with water. 268 In terms of the basic elementary qualities, this means that the earth is predominantly 'dry' in its northern half, and 'moist' in its southern.

269 In this fact we have a symbol which tells us that the earth represents a polarity of the second order, with its 'salt'-pole in the north and its 'sulphur'-pole in the south. 270 Hence the magnetism called 'North' must be of saline and therefore spherical nature, corresponding to the negative pole in the realm of electricity, while 'South' magnetism must be of sulphurous-- i.e. radial-nature, corresponding to positive electricity. 271 Moreover, this must hold good equally for the fields of magnetic force generated by naturally magnetic or artificially magnetized pieces of iron. 272 For the circumstance that makes a piece of matter into a magnet is simply that part of the general magnetic field of the earth has been drawn into it. 273 Of especial interest in this respect is the well-known dependence of the direction of an electrically produced magnetic field on the position of the poles of the electric field.

274 The insight we have now gained into the nature of electricity has led us to the realisation that with every act of setting electromagnetic energies in motion we interfere with the entire levity-gravity balance of our planet by turning part of the earth's coherent substance into cosmic 'dust'. 275 Remembering our picture of radioactivity, in which we recognised a sign of the earth's old age, we may say that whenever we generate electricity we speed up the earth's process of cosmic ageing. 276 Obviously this is tremendously enhanced by the creation of artificial radioactivity along the lines recently discovered, 277 whereby it has now become possible to transmute chemical elements into one another, or even to cancel altogether their gravity-bound existence.

278 To see things in this light is to realise that with our having become able to rouse electricity and magnetism from their dormant state and make them work for us, a

gigantic responsibility has devolved upon humankind. 279 It was human's fate to remain unaware of this fact during the first phase of the electrification of your civilisation; to continue now in this state of unawareness would spell peril to the human race.

280 The fact that modern science has long ceased to be a 'natural' science is something which has begun to dawn upon the modern scientific researcher. 281 What has thus come to him as a question finds a definite answer in the picture of electricity we have been able to develop. 282 It is again Eddington who has drawn attention particularly to this question: see the chapter, 'Discovery or Manufacture?' in his *Philosophy of Physical Science*. 283 It will be appropriate at this point to recall his remarks, for they bear not only on the outcome of our own present discussion, but also, as the next chapter will show, on the further course of our studies.

284 Eddington starts by asking: 'When Lord Rutherford showed us the atomic nucleus, did he find it or did he make it?' 285 Whichever answer we give, Eddington goes on to say, makes no difference to our admiration for Rutherford himself. But it makes all the difference to our ideas on the structure of the physical universe. 286 To make clear where the modern physicist stands in this respect, Eddington uses a striking comparison. 287 If a sculptor were to point in our presence to a raw block of marble saying that the form of a human head was lying hidden in the block, 'all our rational instinct would be roused against such an anthropomorphic speculation'. 288 For it is inconceivable to us that Nature should have placed such a form inside the block. Roused by our objection, the artist proceeds to verify his theory experimentally--'with quite rudimentary apparatus, too: 289 merely using a chisel to separate the form for our inspection, he triumphantly proves his theory.'

290 'Was it in this way', Eddington asks, 'that Rutherford rendered concrete the nucleus which his scientific imagination had created?' 291 One thing is certain: 'In every physical laboratory we

see ingeniously devised tools for executing the work of sculpture, according to the designs of the theoretical physicist. 292 Sometimes the tool slips and carves off an odd-shaped form which the physicist had not expected. Then we have a new experimental discovery,'

293 To this analogy Eddington adds the following even more drastic one: 'Procrustes, you will remember,' he says, 'stretched or chopped down his guests to fit the bed he constructed. 294 But perhaps you have not heard the rest of the story. He measured them up before they left the next morning, and wrote a learned paper '*On the Uniformity of Stature of Travellers for the Anthropological Society of Attica*.'

295 Besides yielding a definite answer to the question of how far the seemingly discovered facts of science are manufactured facts, 296 our newly won insight into the nature of the electric and magnetic polarties throws light also on the possibility of so handling both that their application will lead no longer to a cancellation, but to a true continuation, of Nature's own creative deeds.

COLOURS AS 'DEEDS AND SUFFERINGS OF LIGHT'

Ernst Lehrs

14 'As for what I have done as a poet, I take no pride in it whatever. Excellent poets have lived at the same time as myself; poets more excellent have lived before me, and others will come after me. 2 But that in my century I am the only person who knows the truth in the difficult science of colours--of that, I say, I am not a little proud, and here I have a consciousness of a superiority to many.'

3 In these words spoken to his secretary, Eckermann, in 1829, a few years before his death, Goethe gave his opinion on the significance of his scientific researches in the field of optical phenomena. 4 He knew that the path he had opened up had led him to truths which belong to the original truths of humankind. He expressed this by remarking that

his theory of colour was 'as old as the world'.

5 If in this book we come somewhat late to a discussion of Goethe's colour-theory, in spite of the part it played in his own scientific work, and in spite of its significance for the founding of a physics based on his method, the reasons are these. 6 When Goethe undertook his studies in this field he had not to reckon with the forms of thought which have become customary since the development of mechanistic and above all - to put it concisely - of 'electricalistic' thinking. 7 Before a hearing can be gained in our age for a physics of Light and Colour as conceived by Goethe, certain hindrances must first be cleared away. 8 So a picture on the one hand of matter, and on the other of electricity, such as is given when they are studied by Goethean methods, had first to be built up; 9 only then is the ground provided for an unprejudiced judgment of Goethe's observations and the deductions that can be made from them to-day.

10 As Professor Heisenberg, in his lecture quoted earlier (Chapter-2), rightly remarks, Goethe strove directly with Newton only in the realms of colour-theory and optics. 11 Nevertheless his campaign was not merely against Newton's opinions in this field. He was guided throughout by the conviction that the fundamental principles of the whole Newtonian outlook were at stake. 12 It was for this reason that his polemics against Newton were so strongly expressed, although he had no fondness for such controversies.13 In looking back on that part of the Farbenlehre which he had himself called 'Polemical' in the title, he said to Eckermann: 'I by no means disavow my severe dissections of the Newtonian statements; 14 it was necessary at the time and will also have its value hereafter; but at bottom all polemical action is repugnant to my nature, and I can take but little pleasure in it.'

15 The reason why Goethe chose optics as the field of conflict, and devoted to it more than twenty years of research and reflexion, amidst all the other labours of his rich life, lay certainly in his individual temperament-- 'zum Sehen geboren, zum Schauen

bestellt'. 16 At the same time one must see here a definite guidance of humanity. Since the hour had struck for humankind to take the first step towards overcoming the world-conception of the one-eyed, colour-blind onlooker, 17 what step could have been more appropriate than this of Goethe's, when he raised the eye's capacity for seeing colours to the rank of an instrument of scientific cognition?

18 In point of fact, the essential difference between Goethe's theory of colour and the theory which has prevailed in science (despite all modifications) since Newton's day, lies in this: 19 While the theory of Newton and his successors was based on excluding the colour-seeing faculty of the eye, Goethe founded his theory on the eye's experience of colour.

20 In view of the present scientific conception of the effect which a prismatic piece of a transparent medium has on light passing through it, 21 Goethe's objection to Newton's interpretation and the conclusions drawn from it seems by no means as heretical as it did in Goethe's own time and for a hundred years afterwards. 22 For, as Lord Rayleigh and others have shown, the facts responsible for the coming into being of the spectral colours, when these are produced by a diffraction grating, invalidate Newton's idea that the optical apparatus serves to reveal colours which are inherent in the original light. 23 Today it is known that these colours are an outcome of the interference of the apparatus (whether prism or grating) with the light. 24 Thus we find Professor R. W. Wood, in the opening chapter of his *Physical Optics*, after having described the historical significance of Newton's conception of the relation between light and colour, 25 saying: 'Curiously enough, this discovery, which we are taking as marking the beginning of a definite knowledge about light, is one which we shall demolish in the last chapter of this book, 26 for our present ideas regarding the action of the prism more nearly resemble the idea held previous to Newton's classical experiments. 27 We now believe that the prism actually manufactures the coloured light.'

28 We find ourselves faced here with an instance of the problem,

'Discovery or Manufacture?' dealt with by Eddington in the manner described in our previous chapter. 29 This very instance is indeed used by Eddington himself as a case in which the answer is definitely in favour of 'manufacture'. 30 Nevertheless, Eddington complains, experts, in spite of knowing better, keep to the traditional way of speaking about the spectral colours as being originally contained in the light. 'Such is the glamour of a historical experiment.' 31 It is for the same reason that Goethe's discovery continues to be unrecognised by the majority of scientists, who prefer, instead of examining the question for themselves, to join in the traditional assertion that 'Goethe never understood Newton'. 32 As Goethe relates at the conclusion of the 'historical' part of his Farbenlehre, he was drawn to study colour by his wish to gain some knowledge of the objective laws of aesthetics. 33 He felt too close to poetry to be able to study it with sufficient detachment, so he turned to painting-- 34 an art with which he felt sufficiently familiar without being connected with it creatively-- hoping that if he could discover the laws of one art they would prove applicable to others.

35 His visit to Italy, a land rich both in natural colour and in works of art, gave him a welcome opportunity to pursue this inquiry, but for a long time he made no headway. 36 The paintings he saw suggested no inherent law in their arrangement of colours, nor could the painters he questioned tell him of one. 37 The only qualitative distinction they seemed to recognise was between 'cold' and 'warm' colours.

38 His own observations led him to a definite experience of the quality of the colour blue, for which he coined the phrase 'feebleness of blue' ('Ohnmacht des Blau'). In some way this colour seemed to him to be related to black. 39 In order to rouse his artist friends and to stimulate their reflexions, he liked to indulge in paradoxes, as when he asserted that blue was not a colour at all. He found, however, as time went on, that in this way he came no nearer his goal.

40 Although the splendour of colour in the Italian sky and the Italian landscape made a powerful

impression on Goethe, 41 he found not enough opportunity for systematic study to allow him to arrive at more than a dim surmise of some law underlying the occurrence of colour in Nature. 42 Still, there was one thing he took home with him as a result of his labours. He had grown convinced that 'the first approach to colours as physical phenomena had to be sought from the side of their occurrence in Nature, if one would gain an understanding of them in relation to art'.

43 Back at home, he strove to recollect the theory of Newton as it was being taught in schools and universities-- namely, that 'colours in their totality are contained in light'. 44 Hitherto he had had no occasion to doubt the correctness of this theory. Like everyone else, he had heard it expounded in lectures as an incontestable result of empirical observation, though without this ever having been shown to him by way of experiment. 45 He convinced himself by consulting a manual that his recollection was correct, but at the same time he found that the theory there set forth gave no help in answering his questions. So he decided to examine the phenomena for himself.

46 For this purpose he borrowed a set of prisms from a friend living in near-by Jena, the physicist, BÃ¼ttner. 47 Since, however, he had at that time no opportunity of arranging a dark chamber on Newton's lines, where the necessary ray of light from a tiny hole in the window-covering was sent through a prism, 48 he postponed the whole thing, until in the midst of all his many other interests and duties it was forgotten. 49 In vain BÃ¼ttner pressed many times for the return of the prisms; at last he sent a mutual acquaintance with the injunction not to return without them. 50 Goethe then searched for the long-neglected apparatus and determined to take a rapid glance through one of the prisms before he gave them back.

51 He recalled dimly his pleasure as a boy at the vision of the world given him through a bit of similarly shaped glass. 'I well remember that everything looked coloured, but in what manner I could no longer recollect. 52 I was

just then in a room completely white; remembering the Newtonian theory, I expected, as I put the prism to my eye, to find the whole white wall coloured in different hues and to see the light reflected thence into the eye, split into as many coloured lights.

53 'But how astonished was I when the white wall seen through the prism remained white after as before. 54 Only where something dark came against it a more or less decided colour was shown, and at last the window-bars appeared most vividly coloured, while on the light-grey sky outside no trace of colouring was to be seen. 55 It did not need any long consideration for me to recognise that a boundary or edge is necessary to call forth the colours, and I immediately said aloud, as though by instinct, that the Newtonian doctrine is false.'

56 For Goethe, there could be no more thought of sending back the prisms, and he persuaded BÃ¼ttner to leave them with him for some time longer. 57 Goethe adds a short account of the progress of the experiments he now undertook as well as of his efforts to interest others in his discovery. 58 He makes grateful reference to those who had brought him understanding, and who had been helpful to him through the exchange of thoughts. 59 Among these, apart from Schiller, whom Goethe especially mentions, we find a number of leading anatomists, chemists, writers and philosophers of his time, but not a single one of the physicists then active in teaching or research. 60 The 'Guild' took up an attitude of complete disapproval or indifference, and so have things remained till a hundred years after his death, as Goethe himself prophesied. 61 One of the first systematic pieces of work which Goethe undertook in order to trace the cause of the Newtonian error was to go through Book-I of Newton's Optics, 62 sentence by sentence, recapitulate Newton's experiments and rearrange them in the order which seemed to him essential. 63 In so doing he gained an insight which was fundamental for all future work, and often proved very beneficial in the perfecting of his own methods. 64 His examination

of the Newtonian procedure showed him that the whole mistake rested on the fact that 'a complicated phenomenon should have been taken as a basis, and the simpler explained from the complex'. 65 Nevertheless, it still needed 'much time and application in order to wander through all the labyrinths with which Newton had been pleased to confuse his successors'.

66 It seems a small thing, and yet it is a great one, which Goethe, as the above description shows, discovered almost by chance. 67 This is shown by the conclusions to which he was led in the systematic prosecutions of his discovery. 68 An account of them is given in his BeitrÃ¤ge zur Optik, published in 1791, the year in which Galvani came before the public with his observations in the sphere of electricity.

69 Goethe describes in this book the basic phenomena of the creation of the prismatic colours, with particulars of a number of experiments so arranged that the truth he had discovered, contrary to Newton's view, comes to light through the very phenomena themselves. 70 Only much later, in the year 1810, and after he had brought to a certain conclusion four years previously the researches which he had pursued most carefully the whole time, 71 did he make public the actual masterpiece, Entwurf einer Farbenlehre. (An English translation of the didactic part appeared about ten years after Goethe's death.)

72 While leaving a more detailed description of the composition of Goethe's Entwurf for our next chapter, we shall here deal at once with some of the essential conclusions to which the reader is led in this book. 73 As already mentioned, Goethe's first inspection of the colour-phenomenon produced by the prism had shown him that the phenomenon depended on the presence of a boundary between light and darkness. 74 Newton's attempt to explain the spectrum out of light alone appeared to him, therefore, as an inadmissible setting aside of one of the two necessary conditions. 75 Colours, so Goethe gleaned directly from the prismatic phenomenon, are

caused by both light and its counterpart, darkness. 76 Hence, to arrive at an idea of the nature of colour, which was in accord with its actual appearance, he saw himself committed to an investigation of the extent to which the qualitative differences in our experience of colours rests upon their differing proportions of light and darkness.

77 It is characteristic of Goethe's whole mode of procedure that he at once changed the question, 'What is colour?' into the question, 'How does colour arise?' 78 It was equally characteristic that he did not, as Newton did, shut himself into a darkened room, so as to get hold of the colour-phenomenon by means of an artificially set-up apparatus. 79 Instead, he turned first of all to Nature, to let Her give him the answer to the questions She had raised. 80 It was clear to Goethe that to trace the law of the genesis of colour in Nature by reading Her phenomena, he must keep a look-out for occurrences of colours which satisfied the conditions of the Ur-phÃ¤nomen, as he had learned to know it. 81 This meant that he must ask of Nature where She let colours arise out of light and darkness in such a way that no other conditions contributed to the effect.

82 He saw that such an effect was presented to his eye when he turned his gaze on the one hand to the blue sky, and on the other to the yellowish luminous sun. 83 Where we see the blue of the heavens, there, spread out before our eyes, is universal space, which as such is dark. 84 Why it does not appear dark by day as well as by night is because we see it through the sun-illumined atmosphere. 85 The opposite role is played by the atmosphere when we look through it to the sun. In the first instance it acts as a lightening, in the second as a darkening, medium. 86 Accordingly, when the optical density of the air changes as a result of its varying content of moisture, the colour-phenomenon undergoes an opposite change in each of the two cases. 87 Whilst with increasing density of the air the blue of the sky brightens up and gradually passes over into white, the yellow of the sun

gradually darkens and finally gives way to complete absence of light.

88 The ur-phenomenon having once been discovered in the heavens, could then easily be found elsewhere in Nature on a large or small scale-as, for instance, in the blue of distant hills when the air is sufficiently opaque, 89 or in the colour of the colourless, slightly milky opal which looks a deep blue when one sees it against a dark background, and a reddish yellow when one holds it against the light. 90 The same phenomenon may be produced artificially through the clouding of glass with suitable substances, as one finds in various glass handicraft objects. 91 The aesthetic effect is due to the treated glass being so fashioned as to present continually changing angles to the light, when both colour-poles and all the intermediate phases appear simultaneously. 92 It is also possible to produce the ur-phenomenon experimentally by placing a glass jug filled with water before a black background, illuminating the jug from the side, and gradually clouding the water by the admixture of suitable substances. 93 Whilst the brightness appearing in the direction of the light goes over from yellow and orange to an increasingly red shade, the darkness of the black background brightens to blue, which increases and passes over to a milky white.

94 It had already become clear to Goethe in Italy that all colour-experience is based on a polarity, which he found expressed by painters as the contrast between 'cold' and 'warm' colours. 95 Now that the coming-into-being of the blue of the sky and of the yellow of the sun had shown themselves to him as two processes of opposite character, he recognised in them the objective reason why both colours are subjectively experienced by us as opposites. 96 'Blue is illumined darkness--yellow is darkened light'-- thus could he assert the urphenomenon, while he expressed the relation to Light of colours in their totality by saying: '*Colours are Deeds and Sufferings of Light*.'

97 With this, Goethe had taken the first decisive step towards his goal-- the tracing of human's

aesthetic experience to objective facts of Nature.

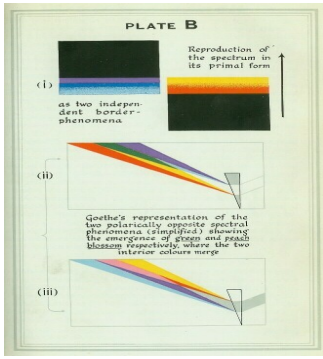
98 If we use the expressions of preceding chapters, we can say that Goethe, in observing the coloured ur-phenomenon, had succeeded in finding how from the primary polarity, Light-Dark, the opposition of the yellow and blue colours arises as a secondary polarity. 99 For such an interplay of light and darkness, the existence of the air was seen to be a necessary condition, representing in the one case a lightening, in the other, a darkening element. 100 That it was able to play this double role arose from its being on the one hand pervious to light, while yet possessing a certain substantial density. For a medium of such a nature Goethe coined the expression trÃ¼bes Medium.

101 There seems to be no suitable word in English for rendering the term trÃ¼be in the sense in which Goethe used it to denote the optical resistance of a more or less transparent medium. 102 The following remarks of Goethe's, reported by his secretary Riemer, will give the reader a picture of what Goethe meant by this term, clear enough to allow us to use the German word. 103 Goethe's explanation certainly shows how inadequate it is to translate trÃ¼be by 'cloudy' or 'semi-opaque' as commentators have done. 104 'Light and Dark have a common field, a space, a vacuum in which they are seen to appear. This space is the realm of the transparent. 105 Just as the different colours are related to Light and Dark as their creative causes, so is their corporeal part, their medium, TrÃ¼be, related to the transparent. 106 The first diminution of the transparent, i.e. the first slightest filling of space, the first disposition, as it were, to the corporeal, i.e. the non-transparent - this is TrÃ¼be.'

107 After Goethe had once determined from the macrotelluric phenomenon that an interplay of light and darkness within TrÃ¼be was necessary for the appearance of colour in space, 108 he had no doubt that the prismatic colours, too, could be understood only through the coming together of all these three elements. 109 It was now his task to examine in what way the prism, by its being

trÃ¼be, brings light and darkness, or, as he also expressed it, light and shadow, into interplay, when they meet at a boundary.

110 We must remember that on first looking through the prism Goethe had immediately recognised that the appearance of colour is always dependent on the existence of a boundary between light and darkness-- in other words, that it is a border phenomenon. 111 What colours appear on such a border depends on the position of light and darkness in relation to the base of the prism. 112 If the lighter part is nearer to the base, then blue and violet tints are seen at the border, and with the reverse position tints of yellow and red (Plate B, Fig. i).



113 Along this path of study Goethe found no reason for regarding the spectrum-phenomenon as complete only when both kinds of border-phenomena appear simultaneously 114 let alone when-- as a result of the smallness of the aperture through which the light meets the prism-- the two edges lie so close that a continuous band of colour arises. 115 Hence we find Goethe-- unlike Newton-- treating the two ends of the spectrum as two separate phenomena.

116 In this way, the spectrum phenomenon gave Goethe confirmation that he had succeeded in expressing in a generally valid form the law of the origin of the blue and the yellow colours, as he had read it from the heavens. 117 For in the spectrum, too, where the colour blue appears, there he saw darkness being lightened by a shifting of the image of the border between light and dark in the direction of darkness; 118 where yellow appears, he saw light being darkened by a shifting of the image in the direction of light. (See the arrow in Plate B, Fig. I above.)

119 In the colours adjoining these-- indigo and violet on the blue side,

orange and red on the yellow side-- Goethe recognised 'heightened' modifications of blue and yellow. 120 Thus he had learn't from the macro-telluric realm that with decreasing density of the corporeal medium, the blue sky takes on ever deeper tones, while with increasing density of the medium, the yellow of the sunlight passes over into orange and finally red. 121 Prismatic phenomenon and macrotelluric phenomenon were seen to correspond in this direction, too.

122 Faithful to his question, 'How does colour arise?' Goethe now proceeded to investigate under what conditions two borders, when placed opposite each other, provide a continuous band of colour-- 123 that is, a colour-band where, in place of the region of uncoloured light, green appears. 124 This, he observed, came about if one brought one's eye, or the screen intercepting the light, to that distance from the prism where the steadily widening yellow-red and the blue-violet colour-cones merge (See Plate-B, Fig.ii above). 125 Obviously, this distance can be altered by altering the distance between the two borders. In the case of an extremely narrow light-space, the blue and yellow edges will immediately overlap. 126 Yet the emergence of the green colour will always be due to a union of the blue and yellow colours which spread from the two edges. 127 This convinced Goethe that it is inadmissible to place the green in the spectrum in line with the other colours, as is customary in the explanation of the spectrum since Newton's time.

128 This insight into the relation of the central colour of the continuous spectrum to its other colours still further strengthened Goethe's conviction that in the way human experiences Nature in own soul, objective laws-of-Nature come to expression. 129 For just as we experience the colours on the blue side of the spectrum as cold colours, and those on the yellow side as warm colours, so does green give human the impression of a neutral colour, influencing us in neither direction. 130 And just as the experience of the two polar colour-ranges is an expression of the objective natural law behind them, so too is the

experience of green, the objective conditions of whose origin give it a neutral position between the two. 131 With this it also became clear why the vegetative part of the plant organism, the region of leaf and stem formation, where the light of the sun enters into a living union with the density of earthly substance, must appear in a garment of green.

132 Having in this way found the clue to the true genesis of the spectrum, Goethe could not fail to notice that it called for another-- a 'negative' spectrum, its polar opposite-- to make the half into a whole. 133 For he who has once learn't that light and darkness are two equally essential factors in the birth of colour, 134 and that the opposing of two borders of darkness so as to enclose a light is a 'derived' (abgeleitet) experimental arrangement, 135 is naturally free to alter the arrangement and to supplement it by reversing the order of the two borders, thus letting two lights enclose a darkness between them.

136 If one exposes an arrangement like this to the action of the prism, whose position has remained unchanged, colours appear on each of the two edges, as before, but in reverse order (Fig. iii). 137 The spectral phenomenon now begins at one side with light blue and passes into indigo and violet, with uncoloured darkness in the centre. 138 From this darkness it emerges through red and passes through orange to yellow at the other end.

139 Again, where the two interior colour-cones merge, there an additional colour appears. Like green, it is of a neutral character, but at the same time its quality is opposite to that of green. 140 In Newtonian optics, which assumes colour to be derived from light only, this colour has naturally no existence. 141 Yet in an optics which has learn't to reckon with both darkness and light as generators of colour, the complete spectrum phenomenon includes this colour equally with green. 142 For lack of an existing proper name for it, Goethe termed it 'pure red'-- since it was free from both the blue tinge of the mauve, and the yellow tinge of the red end of the ordinary spectrum, 143 or 'peach-blossom' (pfirsichblÃ¼t), or 'purple' (as being nearest to the

dye-stuff so called by the ancients after the mollusc from which it was obtained).

144 It needs only a glance through the prism into the sunlit world to make one convinced of the natural appearing of this delicate and at the same time powerfully luminous colour. 145 For a narrow dark object on a light field is a much commoner occurrence in Nature than the enclosing by two broad objects of a narrow space of light, the condition necessary for the emergence of a continuous colour-band with green in the middle. 146 In fact, the spectrum which science since the time of Newton regards as the only one, appears much more rarely among natural conditions than does Goethe's counter-spectrum.

147 With the peach-blossom a fresh proof is supplied that what human experiences in own soul is in harmony with the objective facts of Nature. 148 As with green, we experience peach-blossom as a colour that leaves us in equilibrium. 149 With peach-blossom, however, the equilibrium is of a different kind, owing to the fact that it arises from the union of the colour-poles, not at their original stage but in their 'heightened' form. 150 And so green, the colour of the plant-world harmony given by Nature, stands over against 'purple', the colour of the human being striving towards harmony. 151 By virtue of this quality, purple served from antiquity for the vesture of those who have reached the highest stage of human development for their time. 152 This characteristic of the middle colours of the two spectra was expressed by Goethe when he called green 'real totality', and peach-blossom 'ideal totality'.

153 From this standpoint Goethe was able to smile at the Newtonians. He could say that if they persisted in asserting that the colourless, so-called 'white' light is composed of the seven colours of the ordinary spectrum-- red, orange, yellow, green, blue, indigo, violet-- 154 then they were in duty bound to maintain also that the colourless, 'black' darkness is composed of the seven colours of the inverted spectrum-- yellow, orange, red, purple, violet, indigo, blue.

155 Despite the convincing force of this argument, the voice of the Hans Andersen child speaking through Goethe failed to gain a hearing among the crowd of Newtonian faithful. 156 So has it been up to the present day-- regardless of the fact that, as we have shown, modern physics has reached results which make a contradiction of the Newtonian concept of the mutual relation of light and colour no longer appear so heretical as it was in Goethe's time.

157 When we compare the way in which Goethe, on the one hand, and the physical scientist, on the other, have arrived at the truth that what Newton held to be 'discovery' was in actual fact 'manufacture', 158 we find ourselves faced with another instance of a fact which we have encountered before in our study of electricity. 159 It is the fact that a truth, which reveals itself to the spectator-scientist only as the result of a highly advanced experimental research, 160 can be recognised through quite simple observation when this observation is carried out with the intention of letting the phenomena themselves speak for their 'theory'. 161 Furthermore, there is a corresponding difference in the effect the knowledge of such truth has on the human mind. 162 In the field of electricity we saw that together with the scientist's recognition of the absolute qualities of the two polar forms of electricity a false semblance of reality was lent to the hypothesis of the atomic structure of matter. 163 Something similar has occurred in the field of optics. Here, after having been forced to recognise the fallacy of Newton's theory, the spectator's mind has been driven to form a concept of the nature of light which is further than ever from the truth. 164 For what then remains of light is-- in Eddington's words-- a 'quite irregular disturbance, with no tendency to periodicity', which means that to light is assigned the quality of an undefined chaos (in the negative sense of this word) sprung from pure chance. 165 Moreover, as Eddington shows, the question whether the optical contrivance 'sorts out' from the chaotic light a particular periodicity, or whether it

'impresses' this on the light, becomes just 'a matter of expression'. 166 So here, too, the modern investigator is driven to a resigned acknowledgment of the principle of Indeterminacy.

167 No such conclusions are forced upon the one who studies the spectrum phenomenon with the eyes of Goethe. Like the modern experimenter, he, too, is faced with the question 'Discovery or Manufacture?' and he, too, finds the answer to be 'Manufacture'. 168 But to him Nature can disclose Herself as the real manufacturer, showing him how She goes to work in bringing about the colours, 169 because in following Goethe he is careful to arrange his observations in such a way that they do not veil Nature's deeds.

SEEING AS 'DEED' – I

Ernst Lehrs

15 Having made ourselves so far acquainted with the fundamentals of Goethe's approach to the outer phenomena of colour involved in the spectrum, we will leave this for a while to follow Goethe along another no less essential line of inquiry. 2 It leads us to the study of our own process of sight, by means of which we grow aware of the optical facts in outer space.

3 The importance which Goethe himself saw in this aspect of the optical problem is shown by the place he gave it in the didactic part of his *Farbenlehre*. 4 The first three chapters, after the Introduction, are called 'Physiological Colours', 'Physical Colours', and 'Chemical Colours'. 5 In the first chapter, Goethe summarises a group of phenomena which science calls 'subjective' colours, since their origin is traced to events within the organ of sight. 6 The next chapter deals with an actual physics of colour-- that is, with the appearance of colours in external space as a result of the refraction, diffraction and polarisation of light. 7 The third chapter treats of material colours in relation to chemical and other influences. 8 After two chapters which need not concern us here comes the sixth and last chapter, entitled 'Physical-Moral Effect of Colour' ('Sinnlich-sittliche Wirkung der Farben'), which crowns the whole. 9 There, for the

first time in the history of modern science, a bridge is built between Physics, Aesthetics and Ethics. 10 We remember it was with this aim in view that Goethe had embarked upon his search for the solution of the problem of colour.

11 In this chapter the experiencing of the various colours and their interplay through the human soul is treated in many aspects, 12 and Goethe is able to show that what arises in human's consciousness as qualitative colour-experience is nothing but a direct 'becoming-inward' of what is manifested to the 'reader's' eye and mind as the objective nature of colours. 13 So, in one realm of the sense-world, Goethe succeeded in closing the abyss which divides existence and consciousness, so long as the latter is restricted to a mere onlooker-relationship towards the sense-world.

14 If we ask what induced Goethe to treat the physiological colours before the physical colours, thus deviating so radically from the order customary in science, we shall find the answer in a passage from the Introduction to his Entwurf. 15 Goethe, in giving his views on the connexion between light and the eye, says: 'The eye owes its existence to light. 16 Out of indifferent auxiliary animal organs the light calls forth an organ for itself, similar to its own nature; thus the eye is formed by the light, for the light, so that the inner light can meet the outer.' 17 In a verse, which reproduces in poetic form a thought originally expressed by Plotinus, Goethe sums up his idea of the creative connexion between eye and light as follows:

18 Unless our eyes had something of the sun, How could we ever look upon the light? Unless there lived within us God's own might, How could the Godlike give us ecstasy? (Trans. Stawell-Dickinson)

19 By expressing himself in this way in the Introduction to his Farbenlehre, Goethe makes it clear from the outset that when he speaks of 'light' as the source of colour-phenomena, he has in mind an idea of light very different from that held by modern physics. 20 For in dealing with optics, physical science turns at once to phenomena of light found outside

human-- 21 in fact to phenomena in that physical realm from which, as the lowest of the kingdoms of Nature, the observations of natural science are bound to start. 22 Along this path one is driven, as we have seen, to conceive of light as a mere 'disturbance' in the universe, a kind of irregular chaos. 23 In contrast to this, Goethe sees that to gain an explanation of natural physical phenomena which will be in accord with Nature, we must approach them on the path by which Nature brings them into being. 24 In the field of light this path is one which leads from light as creative agent to light as mere phenomenon. 25 The highest form of manifestation of creative light most directly resembling its Idea is within human. 26 It is there that light creates for itself the organ through which, as manifest light, it eventually enters into human consciousness. 27 To Goethe it was therefore clear that a theory of light, which is to proceed in accord with Nature, should begin with a study of the eye: its properties, its ways of acting when it brings us information of its deeds and sufferings in external Nature. 28 The eye with its affinity to light comes into being in the apparently dark space of the mother's womb. 29 This points to the possession by the human organism of an 'inner' light which first forms the eye from within, in order that it may afterwards meet the light outside. 30 It is this inner light that Goethe makes the starting-point of his investigations, and it is for this reason that he treats physiological colours before physical colours. 31 Of fundamental significance as regards method is the way in which Goethe goes on from the passage quoted above to speak of the activity of the inner light: 32 'This immediate affinity between light and the eye will be denied by none; to consider them identical in substance is less easy to comprehend. 33 It will be more intelligible to assert that a dormant light resides in the eye, and that this light can be excited by the slightest cause from within or from without. 34 In darkness we can, by an effort of imagination, call up the brightest images; in dreams, objects appear to us as in broad daylight; 35 if we are awake, the slightest external action of light is

perceptible, and if the organ suffers a mechanical impact light and colours spring forth.'

36 What Goethe does here is nothing less than to follow the development of sight to where it has its true origin. 37 Let us remember that a general source of illusion in the modern scientific picture of the world lies in the fact that the onlooker-consciousness accepts itself as a self-contained ready-made entity, 38 instead of tracing itself genetically to the states of consciousness from which it has developed in the course of evolution. 39 In reality, the consciousness kindled by outer sense-perception was preceded by a dreaming consciousness, and this by a sleeping consciousness, both for the individual and for humanity as a whole. 40 So, too, outer vision by means of the physical apparatus of the eye was preceded by an inner vision. 41 In dreams we still experience this inner vision; we use it in the activity of our picture-forming imagination; and it plays continuously upon the process of external sight. 42 Why we fail to notice this when using our eye in the ordinary way, is because of that dazzling process mentioned earlier in this book. 43 Goethe's constant endeavour was not to become the victim of this blindness-- that is, not to be led by day-time experience to forget the night-side of human life. 44 The passage quoted from the Introduction to his Farbenlehre shows how, in all that he strove for, he kept this goal in view.

45 How inevitably a way of thinking that seeks an intuitive understanding of Nature is led to views like those of Goethe is shown by the following quotations from Reid and Ruskin, 46 expressing their view of the relationship between the eye, or the act of seeing, and external optical phenomena. 47 In his Inquiry, at the beginning of his review of visual perceptions, Reid says:

'The structure of the eye, and of all its appurtenances, the admirable contrivances of Nature for performing all its various external and internal motions and the variety in the eyes of different animals, 48 suited to their several natures and ways of life, clearly demonstrate this organ to be a

masterpiece of Nature's work. 49 And he must be very ignorant of what hath been discovered about it, or have a very strange cast of understanding, who can seriously doubt, whether or not the rays of light and the eye were made for one another with consummate wisdom, and perfect skill in optics."

50 The following passage from Ruskin's Ethics of the Dust (Lecture-X) brings out his criticism of the scientific way of treating of optical phenomena:

51 'With regard to the most interesting of all their [the philosophers'] modes of force-light; they never consider how far the existence of it depends on the putting of certain vitreous and nervous substances into the formal arrangement which we call an eye. 52 The German philosophers began the attack, long ago, on the other side, by telling us there was no such thing as light at all, unless we choose to see it. 53 Now, German and English, both, have reversed their engines, and insist that light would be exactly the same light that it is, though nobody could ever see it. 54 The fact being that the force must be there, and the eye there, and 'light' means the effect of the one on the other-- 55 and perhaps, also-- Plato saw farther into that mystery than anyone has since, that I know of-- on something a little way within the eyes.'

56 Remarks like these, and the further quotation given below, make it seem particularly tragic that Ruskin apparently had no knowledge of Goethe's Farbenlehre. 57 This is the more remarkable in view of the significance which Turner, with whom Ruskin stood in such close connexion, ascribed to it from the standpoint of the artist. 58 For the way in which Ruskin in his Modern Painters speaks of the effect of the modern scientific concept of colours upon the ethical-religious feeling of human, shows that he deplores the lack of just what Goethe had long since achieved in his Farbenlehre where, 59 starting with purely physical observations, he had been able to develop from them a 'physical-moral' theory of colour.

60 Ruskin's alertness to the effect on ethical life of a scientific

world-picture empty of all qualitative values led him to write: 'It is in raising us from the first state of inactive reverie to the second of useful thought, that scientific pursuits are to be chiefly praised. 61 But in restraining us at this second stage, and checking the impulses towards higher contemplation, they are to be feared or blamed. 62 They may in certain minds be consistent with such contemplation, but only by an effort; 63 in their nature they are always adverse to it, having a tendency to chill and subdue the feelings, and to resolve all things into atoms and numbers. 64 For most people, an ignorant enjoyment is better than an informed one, it is better to conceive the sky as a blue dome than a dark cavity, and the cloud as a golden throne than a sleety mist. 65 I much question whether anyone who knows optics, however religious he may be, can feel in equal degree the pleasure and reverence an unlettered peasant may feel at the sight of a rainbow.'

66 What Ruskin did not guess was that the rudiments of the 'moral theory of light' for which he craved, as this passage indicates, had been established by Goethe long before.

67 In the section of his Farbenlehre dealing with 'physiological colours', Goethe devotes by far the most space to the so-called 'afterimages' which appear in the eye as the result of stimulation by external light, and persist for some little time. 68 To create such an afterimage in a simple way, one need only gaze at a brightly lit window and then at a faintly lit wall of the room. 69 The picture of the window appears there, but with the light-values reversed: the dark cross-bar appears as light, and the bright panes as dark.

70 In describing this phenomenon Goethe first gives the usual explanation, that the part of the retina which was exposed to the light from the window-panes gets tired, and is therefore blunted for further impressions, 71 whereas the part on which the image of the dark frame fell is rested, and so is more sensitive to the uniform impression of the wall. 72 Goethe, however, at once adds that although this explanation may

seem adequate for this special instance, there are other phenomena which can be accounted for only if they are held to derive from a 'higher source'. 73 Goethe means experiences with coloured after-images. This will be confirmed by our own discussion of the subject.

74 What we first need, however, is a closer insight into the physiological process in the eye which causes the after-images as such. 75 Wherever Goethe speaks of a simple activity of the retina, we are in fact concerned with a co-operation of the retina with other parts of our organ of sight. 76 In order to make this clear, let us consider how the eye adapts itself to varying conditions of light and darkness. 77 It is well known that if the eye has become adjusted to darkness it is dazzled if suddenly exposed to light, even though the light be of no more than quite ordinary brightness. 78 Here we enter a border region where the seeing process begins to pass over into a pathological condition. 79 A 'secret' of the effect of light on the eye is here revealed which remains hidden in ordinary vision, for normally the different forces working together in the eye hold each other in balance, so that none is able to manifest separately. 80 This equilibrium is disturbed, however, when we suddenly expose the eye to light while it is adapted to darkness. 81 The light then acts on the eye in its usual way, but without the immediate counter-action which normally restores the balance. 82 Under these conditions we notice that the sudden dazzling has a painful influence on the eye-- that is, an influence in some way destructive. 83 This will not seem surprising if we remember that when light strikes on the background of the eye, consciousness is quickened, and this, as we know, presupposes a breaking down of substance in some part of the nervous system. 84 Such a process does in fact occur in the retina, the nerve-part of the eye, when external light falls upon it. 85 If the eye were solely a structure of nerves, it would be so far destroyed by the impact of light that it could not be restored even by sleep, as are the more inward parts of the nervous system. 86 But the eye receives

also a flow of blood, and we know that throughout the threefold human organism the blood supplies the nervous system with building-up forces, polarically opposite to the destructive ones. 87 In sleep, as we have already seen, the interruption of consciousness allows the blood to inundate the nervous system, as it were, with its healing, building-up activity. 88 It is not necessary, however, for the whole of the body to pass into a condition of sleep before this activity can occur. 89 It functions to some extent also in the waking state, especially in those parts of the organism which, like the eye, serve in the highest degree the unfolding of consciousness.

90 Having established this, we have a basis for an understanding of the complete process of vision. 91 We see that it is by no means solely the nerve part of the eye which is responsible for vision, as the spectator-physiology was bound to imagine. 92 The very fact that the place where the optic nerve enters the eye is blind indicates that the function of mediating sight cannot be ascribed to the nerve alone. 93 What we call 'seeing' is far more the result of an interplay between the retina carrying the nerves, and the choroid carrying the blood-vessels. 94 In this interplay the nerves are the passive, receptive organ for the in-working of external light, while the blood-activity comes to meet the nerve-process with a precisely correlated action. 95 In this action we find what Goethe called the 'inner light'. The process involved in adaptation now becomes comprehensible. 96 The cause of the dazzling effect of light of normal intensity on an eye adapted to the dark, is that in such an eye the blood is in a state of rest, and this prevents it from exercising quickly enough the necessary counter-action to the influence of the light. 97 A corresponding effect occurs when one suddenly exposes to darkness the eye adapted to light. 98 One can easily observe what goes on then, if, after looking for a time at an undifferentiated light surface such as the evenly luminous sky, one covers the opened eyes with the hollowed hands. 99 It will then be found that the space before the eyes is filled by a sort of white light, and by

paying close attention one recognises that it streams from the eyes out into the hollowed space. 100 It may even be several minutes before the field of vision really appears black, that is, before the activity of the inner light in the choroid has so far died away that equilibrium prevails between the non-stimulated nerves and the non-stimulated blood.

101 With this insight into the twofold nature of the process of vision we are now able to describe more fully the negative after-image. 102 Although in this case, as Goethe himself remarked, the ordinary explanation seems to suffice, yet in view of our later studies it may be well to bring forward here this wider conception.

103 On the basis of our present findings it is no longer enough to trace the appearing of the after-image solely to a differential fatigue in the retina. 104 The fact is that as long as the eye is turned to the bright window-pane a more intensive blood-activity occurs in the portions of the eye's background met by the light than in those where the dark window-bar throws its shadow on the retina. 105 If the eye so influenced is then directed to the faintly illumined wall of the room, the difference in the activity of the blood persists for some time. 106 Hence in the parts of the eye adapted to darkness we experience the faint brightness as strongly luminous, even dazzling, whereas in the parts more adapted to light we feel the same degree of brightness to be dark. 107 That the action of the inner light is responsible for the differences becomes clear if, while the negative after-image is still visible, we darken the eye with the hollowed hands. 108 Then at once in the dark field of vision the positive facsimile of the window appears, woven by the activity of the blood which reproduces the outer reality.

109 Having traced the colourless after-image to 'higher sources'--that is, to the action of the blood--let us now examine coloured afterimages. 110 We need first to become conscious of the colour-creating light-activity which resides in the blood. For this purpose we expose the eyes for a

moment to an intense light, and then darken them for a sufficient time.

111 Nothing in external Nature resembles in beauty and radiance the play of colour which then arises, unless it be the colour phenomenon of the rainbow under exceptionally favourable circumstances.

112 The physiological process which comes to consciousness in this way as an experience of vision is exactly the same as the process which gives us experiences of vision in dreams. 113 There is indeed evidence that when one awakens in a brightly lit room out of vivid dreaming, one feels less dazzled than on waking from dreamless sleep. 114 This indicates that in dream vision the blood in the eye is active, just as it is in waking vision. 115 The only difference is that in waking consciousness the stimulus reaches the blood from outside, through the eye, whereas in dreams it comes from causes within the organism. 116 The nature of these causes does not concern us here; it will be dealt with later. 117 For the moment it suffices to establish the fact that our organism is supplied with a definite activity of forces which we experience as the appearance of certain images of vision, no matter from which side the stimulus comes. 118 All vision, physiologically considered, is of the nature of dream vision; that is to say, we owe our day-waking sight to the fact that we are able to encounter the pictures of the outer world, brought to us by the light, with a dreaming of the corresponding after-images.

119 Just as the simple light-dark after-image shows a reversal of light-values in relation to the external picture, so in the coloured afterimages there is a quite definite and opposite relationship of their colours to those of the original picture. 120 Thus, if the eyes are exposed for some time to an impression of the colour red, and then directed to a neutral surface, not too brightly illuminated, one sees it covered with a glimmering green. 121 In this way there is a reciprocal correspondence between the colour-pairs Red-Green, Yellow-Violet, Blue-Orange. 122 To whichever of these six colours one exposes the eye, an

after-image always appears of its contrast colour, forming with it a pair of opposites.

123 We must here briefly recall how this phenomenon is generally explained on Newtonian lines. The starting-point is the assumption that the eye becomes fatigued by gazing at the colour and gradually becomes insensitive to it. 124 According to Newton's theory, if an eye thus affected looks at a white surface, the sum of all the colours comes from there to meet it, while the eye has a reduced sensitivity to the particular colour it has been gazing at. 125 And so among the totality of colours constituting the 'white' light, this one is more or less non-existent for the eye. The remaining colours are then believed to cause the contrasting colour-impression.

126 If we apply the common sense of the Hans Andersen child to this, we see where it actually leads. For it says no less than this: as long as the eye is in a normal condition, it tells us a lie about the world, for it makes white light seem something that in reality it is not. 127 For the truth to become apparent, the natural function of the eye must be reduced by fatigue. 128 To believe that a body, functioning in this way, is the creation of God, and at the same time to look on this God as a Being of absolute moral perfection, would seem a complete contradiction to the Hans Andersen child. 129 In this contradiction and others of the same kind to which nowadays every child is exposed repeatedly and willy-nilly in school lessons and so on-- 130 we must seek the true cause of the moral uncertainty so characteristic of young people today. It was because Ruskin felt this that he called for a 'moral' theory of light.

131 Since Goethe did not judge human from artificially devised experiments, but the latter from human, quite simple reflexions led him to the following view of the presence of the contrasting colour in the coloured after-images. 132 Nature outside human had taught you that life on all levels takes it course in a perpetual interplay of opposites, manifested externally in an interplay of diastole and systole comparable to the process of breathing. 133 He, therefore, traced the interchange of light-values in

colourless after-images to a 'silent resistance which every vital principle is forced to exhibit when some definite condition is presented to it. 134 Thus, inhalation presupposes exhalation; thus every systole, its diastole. 135 When darkness is presented to the eye, the eye demands brightness, and vice versa: it reveals its vital energy, its fitness to grasp the object, precisely by bringing forth out of itself something contrary to the object.'

136 Consequently he summarises his reflexions on coloured afterimages and their reversals of colour in these words: 'The eye demands actual completeness and closes the colour-circle in itself.' 137 How true this is, the law connecting the corresponding colours shows, as may be seen in the following diagram. 138 Here, red, yellow and blue as three primary colours confront the three remaining colours, green, violet and orange in such a way that each of the latter represents a mixture of the two other primary colours.

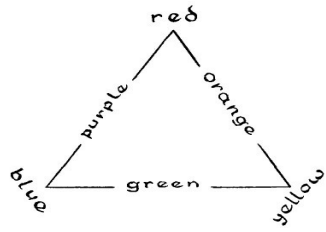


FIG. 10.

(Fig. 10.)

139 Colour and contrast-colour are actually so related that to whatever colour the eye is exposed it produces a counter-colour so as to have the sum-total of all the three primary colours in itself. 140 And so, in consequence of the interplay of outer and inner light in the eye, there is always present in it the totality of all the colours.

141 It follows that the appearance of the contrast-colour in the field of vision is not, as the Newtonian theory asserts, the result of fatigue, but of an intensified activity of the eye, which continues even after the colour impression which gave rise to it has ceased. 142 What is seen on the neutral surface (it will be shown later why we studiously avoid speaking of 'white light') is no outwardly existing colour at all. 143 It is the activity of the eye itself, working in a dreamlike way from its blood-vessel system, and

coming to our consciousness by this means.

144 Here again, just as in the simple opposition of light and dark, the perception of coloured after-images is connected with a breaking-down process in the nerve region of the eye, and a corresponding building-up activity coming from the blood. 145 Only in this case the eye is not affected by simple light, but by light of a definite colouring. 146 The specific destructive process caused by this light is answered with a specific building-up process by the blood. 147 Under certain conditions we can become dreamily aware of this process which normally does not enter our consciousness. In such a case we see the contrasting colour as coloured after-image.

148 Only by representing the process in this way do we do justice to a fact which completely eludes the onlooker-consciousness-- 149 namely, that the eye produces the contrasting colour even while it is still exposed to the influence of the outer colour. 150 Since this is so, all colours appearing to us in ordinary vision are already tinged by the subdued light of the opposite colour, produced by the eye itself. 151 One can easily convince oneself of this through the following experiment. Instead of directing the eye, after it has been exposed to a certain colour, to a neutral surface, as previously, gaze at the appropriate contrasting colour. 152 The first and second coloured surfaces should be so arranged that the former is considerably smaller than the latter. 153 Then, in the middle of the second surface (and in a field about the size of the first), its own colour appears, with a strikingly heightened intensity.

154 Here we find the eye producing, as usual, a contrast-colour from out of itself, as an after-image, even while its gaze is fixed on the same colour in the outer world. 155 The heightened brilliance within the given field is due to the addition of the after-image colour to the external colour.

156 The reader may wonder why this phenomenon is not immediately adduced as a decisive proof of the fallacy of the whole Newtonian theory of the relation

of 'white' light to the various colours. 157 Although it does in fact offer such a proof, we have good reason for not making this use of it here. 158 Throughout this book it is never our intention to enter into a contest of explanations, or to defeat one explanation by another. 159 How little this would help will be obvious if we realise that research was certainly not ignorant of the fact that the opposite colour arises even when the eye is not turned to a white surface. 160 In spite of this, science did not feel its concept of white light as the sum of all the colours to be an error, since it has succeeded in 'explaining' this phenomenon too, and fitting it into the prevailing theory. 161 To do so is in thorough accord with spectator-thinking. Our own concern, however, as in all earlier cases, is to replace this thinking with all its 'proofs' and 'explanations' by learning to read in the phenomena themselves. 162 For no other purpose than this the following facts also are now brought forward.

163 Besides Rudolf Steiner's fundamental insight into the spiritual-physical nature of the growing human being, through which he laid the basis of a true art of education, he gave advice on many practical points. 164 For example, he indicated how by the choice of a suitable colour environment one can bring a harmonising influence to bear on extremes of temperament in little children. 165 To-day it is a matter of practical experience that excitable children are quietened if they are surrounded with red or red-yellow colours, or wear clothes of these colours, 166 whereas inactive, lethargic children are roused to inner movement if they are exposed to the influence of blue or blue-green colours.

167 This psychological reaction of children to colour is not surprising if one knows the role played by the blood in the process of seeing, and how differently the soul-life of human is connected with the blood-nerve polarity of your organism in childhood and in later life. 168 What we have described as the polar interplay of blood and nerve in the act of sight is not confined to the narrow field of the

eye. 169 Just as the nerve processes arising in the retina are continued to the optic centre in the cerebrum, so must we look for the origin of the corresponding blood process not in the choroid itself, but in the lower regions of the organism. 170 Wherever, therefore, the colour red influences the whole nerve system, the blood system as a whole answers with an activity of the metabolism corresponding to the contrasting colour, green. 171 Similarly it reacts as a whole to a blue-violet affecting the nerve system, this time with a production corresponding to yellow-orange.

172 The reason why in later years we notice this so little lies in a fact we have repeatedly encountered. 173 The consciousness of the grown human to-day, through its one-sided attachment to the death-processes in the nerve region, pays no attention to its connexion with the life-processes centred in the blood system. 174 In this respect the condition of the little child is quite different. Just as the child is more asleep in its nerve system than the grown-up person, it is more awake in its blood system. 175 Hence in all sense-perceptions a child is not so much aware of how the world works on its nerve system as how its blood system responds. 176 And so a child in a red environment feels quietened because it experiences, though dimly, how its whole blood system is stimulated to the green production; 177 bluish colours enliven it because it feels its blood answer with a production of light yellowish tones.

178 From the latter phenomena we see once more the significance of Goethe's arrangement of his Farbenlehre. 179 For we are now able to realise that to turn one's attention to the deeds and sufferings of the inner light means nothing less than to bring to consciousness the processes of vision which in childhood, though in a dreamlike way, determine the soul's experience of seeing. 180 Through placing his examination of the physiological colours at the beginning of his Farbenlehre, Goethe actually took the path in scientific research to which Thomas Reid pointed in philosophy. 181 By adapting Reid's words we can say that Goethe, in his Farbenlehre, proclaims as a

basic principle of a true Optics: that we must become again as little children if we would reach a philosophy of light and colours.

SEEING AS 'DEED' – II

Ernst Lehrs

16 The observation of our own visual process, which we began in the last chapter, will serve now to free us from a series of illusory concepts which have been connected by the onlooker-consciousness with the phenomena brought about by light. 2 There is first the general assumption that light as such is visible. In order to realise that light is itself an invisible agent, we need only consider a few self-evident facts-- 3 for instance, that for visibility to arise light must always encounter some material resistance in space. 4 This is, in fact, an encounter between light, typifying levity, and the density of the material world, typifying gravity. 5 Accordingly, wherever visible colours appear we have always to do with light meeting its opposite. 6 Optics, therefore, as a science of the physically perceptible is never concerned with light alone, but always with light and its opposite together. 7 This is actually referred to in Ruskin's statement, quoted in the last chapter, where he speaks of the need of the 'force' and of the intercepting bodily organ before a science of optics can come into existence. 8 Ruskin's 'light', however, is what we have learn't with Goethe to call 'colour', whereas that for which we reserve the term 'light' is called by him simply 'force'.

9 All this shows how illusory it is to speak of 'white' light as synonymous with simple light, in distinction to 'coloured' light. 10 And yet this has been customary with scientists from the time of Newton until today, not excluding Newton's critic, Eddington. 11 In fact, white exists visibly for the eye as part of the manifested world, and is therefore properly characterised as a colour. This is, therefore, how Goethe spoke of it. 12 We shall see presently the special position of white, and likewise of black, as a colour among colours. 13 What matters

first of all is to realise that white must be strictly differentiated from light as such, for the function of light is to make visible the material world without itself being visible.

14 To say that light is invisible, however, does not mean that it is wholly imperceptible. 15 It is difficult to bring the perception of light into consciousness, for naturally our attention, when we look out into light-filled space, is claimed by the objects of the illuminated world, in all their manifold colours and forms. 16 Nevertheless the effect of pure light on our consciousness can be observed during a railway journey, for instance, when we leave a tunnel that has been long enough to bring about a complete adaptation of the eyes to the prevailing darkness. 17 Then, in the first moments of the lightening of the field of vision, and before any separate objects catch the attention, we can notice how the light itself exercises a distinctly expanding influence on our consciousness. 18 We feel how the light calls on the consciousness to participate, as it were, in the world outside the body.

19 It is possible also to perceive directly the opposite of light. This is easier than the direct perception of light, for in the dark one is not distracted by the sight of surrounding objects. 20 One need only pay attention to the fact that, after a complete adapting of the eyes to the dark, one still retains a distinct experience of the extension of the field of vision of both eyes. 21 We find here, just as in the case of light, that our will is engaged within the eye in a definite way; a systolic effect proceeds from dark, a diastolic effect from light. 22 We have a distinct perception of both, but not of anything 'visible' in the ordinary sense.

23 With regard to our visual experience of white and black, it is quite different. We are concerned here with definite conditions of corporeal surfaces, just as with other colours, 24 although the conditions conveying the impressions of white or black are of a special character. 25 A closer inspection of these conditions reveals a property of our act of

seeing which has completely escaped scientific observation, but which is of fundamental importance for the understanding of optical phenomena dynamically.

26 It is well known that a corporeal surface, which we experience as white, has the characteristic of throwing back almost all the light that strikes it, whereas light is more or less completely absorbed by a surface which we experience as black. 27 Such extreme forms of interplay between light and a corporeal surface, however, do not only occur when the light has no particular colour, but also when a coloured surface is struck by light of the same or opposite colour. 28 In the first instance complete reflexion takes place; in the second, complete absorption. And both these effects are registered by the eye in precisely the same manner as those mentioned before. 29 For example, a red surface in red light looks simply white; a green surface in red light looks black.

30 The usual interpretation of this phenomenon, namely, that it consists in a subjective 'contrast' impression of the eye-- 31 a red surface in red light looking brighter, a green surface darker, than its surroundings, and thereby causing the illusion of white or black-- is a typical onlooker-interpretation against which there stands the evidence of unprejudiced observation. 32 The reality of the 'white' and the 'black' seen in such cases is so striking that a person who has not seen the colours of the objects in ordinary light can hardly be persuaded to believe that they are not 'really' white or black. 33 The fact is that the white and the black that are seen under these conditions are just as real as 'ordinary' white and black. 34 When in either instance the eye registers 'white' it registers exactly the same event, namely, the total reflexion of the light by the surface struck by it. 35 Again, when the eye registers 'black' in both cases it registers an identical process, namely, total absorption of the light.

36 Seen thus, the phenomenon informs us of the significant fact that our eye is not at all concerned with the colour of the light that enters its own cavity, but rather

with what happens between the light and the surface on which the light falls. 37 In other words, the phenomenon shows that our process of seeing is not confined to the bodily organ of the eye, but extends into outer space to the point where we experience the visible object to be.

38 This picture of the visual process, to which we have been led here by simple optical observation, was reached by Thomas Reid through his own experience of how, in the act of perceiving the world, human is linked intuitively with it. 39 We remember that he intended in his philosophy to carry ad absurdum the hypothesis that 'the images of the external objects are conveyed by the organs of sense to the brain and are there perceived by the mind'. 40 Common Sense makes Reid speak as follows: 'If any person will shew how the mind may perceive images of the brain, I will undertake to shew how it may perceive the most distant objects; 41 for if we give eyes to the mind, to perceive what is transacted at home in its dark chamber, why may we not make the eyes a little longer-sighted? 42 And then we shall have no occasion for that unphilosophical fiction of images in the brain.' Reid proceeds to show this by pointing out, first, that we must only use the idea of 'image' for truly visual perceptions; 43 secondly, that the sole place of this image is the background of the eye, and not any part of the nervous system lying beyond; 44 thirdly, that even this retina-image, as such, does not come to our consciousness, but serves only to direct the consciousness to the cause of the image, namely, the external object itself. 45 In what follows we shall deal with an observation which will show how right Reid was in this respect.

46 Those familiar with this observation-- well known indeed to those living in the hilly and mountainous districts both here and on the Continent-- 47 know that when distant features of the landscape, in an otherwise clear and sunlit atmosphere, suddenly seem almost near enough to touch, rainy weather is approaching. 48 Likewise a conspicuous increase in distance, while the sky is still

overcast, foreshadows fine weather.

49 This effect (the customary 'explanation' of which is, as usual, of no avail to us and so need not concern us here) ranks with phenomena described in optics under the name of 'apparent optical depth', a subject we shall discuss more fully in the next chapter. 50 It suffices here to state that it is the higher degree of humidity which, by lending the atmosphere greater optical density (without changing its clarity), makes distant objects seem to be closer to the eye, and vice versa. 51 (If we could substitute for the air a much lighter gas-- say, hydrogen-- then the things we see through it would look farther off than they ever do in our atmosphere. 52 Observations such as these show us that (a) when external light strikes the retina of our eye, our inner light is stimulated to move out of the eye towards it; 53 (b) in pressing outward, this inner light meets with a certain resistance, and the extent of this determines at what distance from the eye our visual ray comes to rest as the result of a kind of exhaustion. 54 Just as the outer light reaches an inner boundary at our retina, so does the inner light meet with an outer boundary, set by the optical density of the medium spread out before the eye, 55 Outer and inner light interpenetrate each other along the whole tract between these two boundaries, but normally we are not conscious of this process. 56 We first become conscious of it where our active gaze-- that is, the inner light sent forth through the eye-- reaches the limit of its activity. At that point we become aware of the object of our gaze. 57 So here we find confirmed a fact noted earlier, that consciousness-- at least at its present state of evolution-- arises where for some reason or other our volition conies to rest.

58 The foregoing observations have served to awaken us in a preliminary way to the fact that an essential part of our act of seeing takes place outside our bodily organ of vision 59 and that our visual experience is determined by what happens out there between our gaze and the medium it has to penetrate. 60 Our next task will be to find out how this part of our

visual activity is affected by the properties of the different colours. 61 We shall thereby gain a further insight into the nature of the polarity underlying all colour-phenomena, and this again will enable us to move a step further towards becoming conscious of what happens in our act of seeing.

62 We shall start by observing what happens to the two sides of the colour-scale when the optical medium assumes various degrees of density. 63 For the sky to appear blue by day a certain purity of the atmosphere is needed. 64 The more veiled the atmosphere becomes the more the blue of the sky turns towards white; the purer and rarer the atmosphere, the deeper the blue, gradually approaching to black. 65 To mountain climbers and those who fly at great heights it is a familiar experience to see the sky assume a deep indigo hue. 66 There can be no doubt that at still higher altitudes the colour of the sky passes over into violet and ultimately into pure black. 67 Thus in the case of blue the field of vision owes its darkening to a decrease in the resistance by which our visual ray is met in the optical medium. 68 It is precisely the opposite with yellow. For here, as the density of the medium increases, the colour-effect grows darker by yellow darkening first to orange and then to red, until finally it passes over into complete darkness. 69 This shows that our visual ray is subject to entirely different dynamic effects at the two poles of the colour-scale. 70 At the blue pole, the lightness-effect springs from the resistant medium through which we gaze, a medium under the influence of gravity, 71 while the darkness is provided by the anti-gravity quality of cosmic space, which as a 'negative' resistance exercises a suction on the eye's inner light. 72 At the yellow pole it is just the reverse. Here, the resistant medium brings about a darkening of our field of vision, while the lightness-effect springs from a direct meeting of the eye with light, and so with the suctional effect of negative density.

73 Our pursuit of the dynamic causes underlying our apperception of the two poles of the colour-scale has led us to a point where it becomes necessary

to introduce certain new terms to enable us to go beyond Goethe's general distinction between Finsternis (darkness) and Licht (light). 74 Following Goethe, we have so far used these two terms for what appears both in blue and yellow as the respective light and dark ingredients. 75 This distinction cannot satisfy us any more. For through our last observations it has become clear that the Finsternis in blue and the Licht in yellow are opposites only in appearance, 76 because they are both caused by Levity, and similarly that the lightening effect in blue and the darkening effect in yellow are both effected by Gravity. 77 Therefore, to distinguish between what appertains to the primary polarity, Levity-Gravity, on the one hand, and their visible effects in the secondary polarity of the colours, on the other, 78 we shall henceforth reserve the term darkness and, with it, lightness for instances where the perceptible components of the respective colours are concerned, while speaking of Dark and Light where reference is made to the generating primary polarity.

79 If we are justified in thus tracing the colour-polarity to a polarically ordered interplay between levity and gravity, we may then pursue the following line of thought. 80 We know from earlier considerations that wherever such an interplay between the poles of the primary polarity takes place, we have to do, in geometric terms, with the polarity of sphere and radius. 81 We may therefore conclude that the same characteristics will apply to the way in which the blue of the sky and the yellow of the sunlight are encountered spatially. 82 Now we need only observe how the blue heavens arch over us spherically, on the one hand, and how the yellow brightness of the sun penetrates the air ray-wise, on the other, in order to realise that this really is so.

83 Having thus established the connexion of the two poles of the colour-scale with the spherical and radial structure of space, we are now able to express the Goethean ur-phenomenon in a more dynamic way as follows: 84 On the one

hand, we see the blue of the heavens emerging when levity is drawn down by gravity from its primal invisibility into visible, spherical manifestation. 85 In the yellow of the sunlight, on the other hand, we see gravity, under the influence of the sun's levity, gleaming up radially into visibility. 86 The aspect of the two colour-poles which thus arises before us prompts us to replace Goethe's 'lightened Dark' by Earthward-dawning-Levity, and his 'darkened Light' by Heavenward-raying-Gravity.

87 We have now to show that this picture of the dynamic relationship which underlies the appearance of the colour-polarity in the sky is valid also for other cases 88 which are instances of the ur-phenomenon of the generation of colour in Goethe's sense, but seem not to lend themselves to the same cosmic interpretation. 89 Such a case is the appearance of yellow and blue when we look through a clouded transparent medium towards a source of light or to a black background. 90 There is no special difficulty here in bringing the appearance of yellow into line with its macrotelluric counterpart, but the appearance of blue requires some consideration.

91 We have seen that a corporeal surface appears as black if light striking it is totally absorbed by it. 92 Thus, wherever our eye is met by the colour black, our visual ray is engaged in a process whereby light disappears from physical space. 93 Now we need only bring this process into consciousness-- as we have tried to do before in similar instances-- to realise that what happens here to the visual ray is something similar to what it undergoes when it is directed from the earth into cosmic space.

94 Note, in this respect, the principle of the mirror as another instance of the fact that the interplay between light and an illumined surface can have on the visual ray an effect similar to that of external space. 95 For the optical processes which occur on the surface of a mirror are such that, whilst taking place on a two-dimensional plane, they evoke in our consciousness pictures of exactly the same nature as if we were looking through the mirror into the space behind it.

96 The value of our picture of the colour-polarity is shown further if we observe how natural phenomena based on the same kind of polarity in other realms of nature fit in with it. 97 We remember that one of Goethe's starting-points in his investigation of the riddle of colour was the observation that of the totality of colours one part is experienced as 'warm' and the other as 'cold'. 98 Now we can go further and say that the colours of the spherical pole are experienced as cold, those of the radial pole as warm. This corresponds precisely to the polarity of snow-formation and volcanic activity. 99 The former, being the spherically directed process, requires physically low temperatures; the latter, being the radially directed process, requires high temperatures. 100 Here, once more, we see with what objectivity the human senses register the facts of the outer world.

101 Another realm of phenomena based on a similar polar order is that of electricity. When we studied the negative and positive poles of the vacuum tube, with regard to the polar distribution of radius and sphere, 102 our attention was drawn to the colours appearing on the two electrodes--red at the (positive) anode, blue at the (negative) cathode. Again we find a coincidence with the natural order of the colours.

103 Note how the qualitative dynamic method employed here brings into direct view the relationship between light and electricity, while it precludes the mistake of tracing light processes to those of electricity, as modern science does. 104 Nor are electric processes 'explained' from this point of view merely as variations of light processes. 105 Rather is the relation between light and electricity seen to be based on the fact that all polarities arising perceptibly in Nature are creations of the same primeval polarity, that of Levity and Gravity. 106 The interplay of Levity and Gravity can take on many different forms which are distinguished essentially by differences in cosmic age. 107 Thus the colour-polarity in its primal form, made manifest by the heavens, differs as much from the corresponding polarity shown by the vacuum tube, as does the

lightning in the heights from the electric spark.

108 With the aid of what we have learn't here concerning outer light-processes we shall turn once more to the activity of our own inner light. 109 We may expect by now that our eye is fitted with two modes of seeing activity, polar to each other, 110 and that the way in which they come into operation depends on whether the interplay of positive and negative density outside the eye leads to the appearance of the blue-violet or of the yellow-red side of the colour-scale. 111 Such a polarity in the activity of the eye can indeed be established. Along with it goes a significant functional difference between the two eyes (not unlike that shown of the two hands).

112 To observe this we need simply to compare the two eyes of a person in a photograph by covering alternately the right and the left half of the face. 113 Nearly always it will be found that the right eye looks out clearly into the world with an active expression, and the left eye with a much gentler one, almost held back. 114 Artists are well aware of this asymmetry, as of others in the human countenance, and are careful to depict it. 115 An outstanding example is Raphael's Sistine Madonna, where in the eyes and whole countenance both of Mother and Child this asymmetry can be studied in a specially impressive way.

116 Inner observation leads to a corresponding experience. A convenient method is to exercise the two eyes in complete darkness, in the following way. 117 One eye is made to look actively into the space in front of it, as if it would pierce the darkness with its visual ray, while the activity of the other eye is held back, so that its gaze rests only superficially, as it were, on the darkness in front of it. 118 Experience shows that most people find it natural to give the active note to the right eye, and the passive note to the left. 119 Once one has grown conscious of this natural difference between the two eyes, it is quite easily detected while one is looking normally into the light-filled environment. 120 We thereby realise that for the two eyes to act differently in this way is the usual thing. As an instance

where this fact is well observed and effectively made use of, that of shooting may be mentioned here, especially shooting at flying game. 121 Those who train in this sport learn to make a completely different use of the two eyes in sighting the target. The naturally more active eye-- only once in about fifty cases is it the left-- is called by them the 'master-eye'. 122 Whilst the less actively gazing eye is usually employed for surveying the field as a whole into which the target is expected to enter, the master-eye is used for making active contact with the target itself ('throwing' oneself on the target 'through' the eye).

123 One further observation may be added. If one looks with rested eyes and in very faint daylight (perhaps in the early morning on awakening) at a white surface, while opening and closing the eyes alternately, then the white surface looks faintly reddish to the 'master-eye', and faintly bluish to the other.

124 Following the lines of our treatment of after-images in the last chapter, we will next inquire into the anatomical and physiological basis of the two opposite sight-activities. 125 In the previous instance we found this in the polarity of nerve and blood. This time we must look for it in a certain twofold structure of the eye itself. 126 We shall best perceive this by watching the 'becoming' of the eye, thus again following a method first shown by Goethe.

127 Fig. 11 shows the human eye in different stages of its embryonic formation.

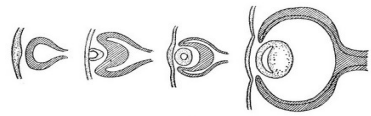

Fig. 11.

128 The eye is clearly seen to consist of two parts essentially different in origin. 129 Growing out from the interior of the embryonic organism is a structure that is gradually pushed in, and in its further development becomes the entire posterior part of the eye, destined to carry its life-imbued functions. 130 A second independent part grows towards this from outside; this is at first a mere thickening of the embryonic skin formation, but later it loosens itself and presses forward into the interior of the cup-shaped structure. 131 It is gradually

enclosed by this, and evolves finally into that part of the finished eye which embodies the optical apparatus functioning according to purely physical laws.

132 This series of forms shows that in the embryonic formation of the eye we are confronted with two processes, one of spherical, and the other of radial orientation. 133 Consequently the two parts of the eye are differentiated in such a way that the posterior part, which has grown forth radially from the embryonic organism, as the life-filled element represents the sulphur-pole of the total eye, 134 while the anterior part, with its much more crystalline nature, having grown spherically towards the organism, represents the eye's salt-pole.

135 Closer inspection into the connexion of the two visual activities of the eye with its basic corporeal parts reveals that here, at the outermost boundary of the human organism, we encounter once more that peculiar reversal of functions which we have already several times met in various realms of Nature. 136 For the anterior part of the eye-- its salt-pole-- which has come into being through a spherically directed formative process, seems to be the one through which we exercise the perceptive activity streaming out radially from the eye, 137 whilst the posterior part-- the eye's sulphur-pole-- which has come into being through radially directed formative action, serves that form of seeing which is more receptive and is carried out in a plane-wise manner.

138 Considerations of this kind, and they alone, enable us also to draw true comparisons between the different sense-organs. 139 Take the organ of hearing. Usually the ear is assumed to fill the same role in the field of hearing as does the eye in the field of seeing. 140 In fact the ear corresponds to only one half of the eye; the other half must be looked for in the larynx. 141 In other words, the two parts of the eye are represented in the realm of hearing by two separate organs, ear and larynx. 142 Speaking from the aspect of metamorphosis, the vital part of our eye may be regarded as our 'light-ear'; the crystalline part, as our 'light-larynx'. 143 In order to

come consciously to a perception of sight we must 'listen' to the 'deeds and sufferings' of light, while at the same time we meet them with the help of the 'speaking' of our inner light. 144 Something similar holds good for hearing. In fact, observation reveals that we take in no impression of hearing unless we accompany it with an activity of our larynx, even though a silent one. 145 The significance of this fact for the total function of hearing will occupy us more fully later.

146 Our insight into the polar nature of visual activity will enable us now to link the external interplay of Light and Dark-- 147 to which the physical colours owe their existence-- to that play of forces which we ourselves set in motion when our eye meets the world of colours in their polar differentiation.

148 We established earlier that in the cold colours the role of darkness belongs to the pole of levity or negative density, and the role of lightness to the pole of gravity or positive density, whereas in the case of the warm colours the roles are reversed. 149 Let us now unite with this the insight we have meanwhile gained into the two kinds of activity in seeing-- the receptive, 'left-eyed' and the radiating, 'right-eyed'-- which mediate to us the experience of the positive or negative density of space spread out before our eyes. 150 Taking together the results of outer and inner observation, we can express the polarity ruling in the realm of colour as follows.

151 If lightness and darkness as elements of colour, meet us in such a way that lightness, by reason of its positive density, calls forth 'left-eyed' activity, and darkness, by reason of its negative density, 'right-eyed' activity, then our soul receives the impression of the colour blue and colours related to blue. 152 If lightness and darkness meet us so that we see the former in a 'right-eyed', and the latter in a 'left-eyed' way, then we experience this as the presence of yellow and the colours related to it.

153 The reason why we usually fail to observe the different kinds of interplay of the two modes of

seeing, when we perceive one or other of the two categories of colour, 154 is because in ordinary sight both eyes exercise each of the two activities without our becoming aware which is the leading one in a particular eye. 155 If, however, one has come to a real experience of the inner polarity of the visual act, one needs only a little practice to realise the distinction. 156 For example, if one looks at the blue sky, notably at noon-time, on the side away from the sun, or at the morning or evening sky, shining yellow and red, 157 one quickly becomes conscious of how our eyes take hold of the particular contribution which Light and Dark make to one or other of the two colour appearances.

158 In the natural course of our argument we had to keep at first to the appearance of colours as they come freely before us in space. 159 The results we have obtained, however, hold good equally well for the permanent tints of material objects, as the following example will show.

160 A fact known to science is that red and blue surface colours, when illumined by light of steadily diminishing intensity, are seen to reverse their normal ratio of brightness. 161 This phenomenon can be seen in Nature, if, for instance, one observes a bed of blue and red flowers in the fading evening light and compares the impression with that which the same flowers make in bright daylight. 162 If the phenomenon is reproduced artificially, the actual transition from one state to the other can be clearly observed. 163 The easiest way is to place a red and a blue surface side by side under an electric light whose intensity can be gradually lessened by means of a sliding resistance. 164 Here, as much as in the natural phenomenon, our reason finds it difficult to acknowledge that the surface gleaming in a whitish sheen should be the one which ordinarily appears as darkling blue, 165 and that the one disappearing into darkness should be the surface which normally presents itself as radiant red.

166 This riddle is readily solved if we apply what we have learn't about the particular shares of lightness and darkness in these two

colours, and if we link this up with the respective forms of seeing exercised by our two eyes. 167 To the dim light, clearly, our eyes will respond more with the 'left-eyed' than with the 'right-eyed' form of vision. 168 Now we know that it is 'left-eyed' vision which is roused by the lightness-component in blue and the darkness-component in red. 169 It is only to be expected, therefore, that these elements should become conspicuous when in the dim light our seeing is mainly 'left-eyed'. 170 This solution of the problem makes us realise further, that the laws which Goethe first found for the coming into appearance of colours freely hovering in space are indeed applicable to the fixed material colours as well.

OPTICS OF THE DOER

Ernst Lehrs

17 Three basic concepts form the foundation for the present-day scientific description of a vast field of optical phenomena, 2 among them the occurrence of the spectral colours as a result of light passing through a transparent medium of prismatic shape. They are: 'optical refraction', 'light-ray', and 'light-velocity'-- the latter two serving to explain the first. 3 In a science of optics which seeks its foundation in the intercourse between human's own visual activity and the doings and sufferings of light, these three concepts must needs undergo a decisive change, both in their meaning and in their value for the description of the relevant optical phenomena. 4 For they are all purely kinematic concepts typical of the onlooker-way of conceiving things-- concepts, that is, to which nothing corresponds in the realm of the actual phenomena.

5 Our next task, therefore, will be, where possible, to fill these concepts with new meaning, or else to replace them by other concepts read from the actual phenomena. 6 Once this is done the way will be free for the development of the picture of the spectrum phenomenon which is in true accord with the Goethean conception of Light and Colour.

7 The first to be brought in this sense under our examination is the concept of the 'light-ray'. 8 In present-day optics this concept

signifies a geometrical line of infinitely small width drawn, as it were, by the light in space, while the cone or cylinder of light actually filling the space is described as being composed of innumerable such rays. 9 In the same way the object producing or reflecting light is thought of as composed of innumerable single points from which the light-rays emerge. All descriptions of optical processes are based upon this conception. 10 Obviously, we cannot be satisfied with such a reduction of wholes into single geometrically describable parts, followed by a reassembling of these parts into a whole. 11 For in reality we have to do with realms of space uniformly filled with light, whether conical or cylindrical in form, which arise through certain boundaries being set to the light. 12 In optical research we have therefore always to do with pictures, spatially bounded. Thus what comes before our consciousness is determined equally by the light calling forth the picture, and by the unlit space bordering it.

13 Remembering the results of our earlier study, we must say further of such a light-filled realm that it lacks the quality of visibility and therefore has no colour, not even white. 14 Goethe and other 'readers', such as Reid and Ruskin, tried continually to visualize what such a light-filled space represents in reality. 15 Hence they directed their attention first to those spheres where light manifests its form-creative activity, as in the moulding of the organ of sight in animal or human, 16 or in the creation of the many forms of the plant kingdom-- and only then gave their mind to the purely physical light-phenomena. 17 Let us use the same method to form a picture of a light-filled space, and to connect this with the ideas we have previously gained on the co-operation in space of levity and gravity.

18 Suppose we have two similar plant-seeds in germ; and let one lie in a space filled with light, the other in an unlit space. 19 From the different behaviour of the two seeds we can observe certain differences between the two regions of space. 20 We note that

within the light-filled region the spiritual archetype of the plant belonging to the seed is helped to manifest itself physically in space, whereas in the dark region it receives no such aid. 21 For in the latter the physical plant, even if it grows, does not develop its proper forms. 22 This tells us, in accordance with what we have learn't earlier, that in the two cases there is a different relation of space to the cosmically distant, all-embracing plane. 23 Thus inside and outside the light-region there exists a quite different relation of levity and gravity-- and this relation changes abruptly at the boundaries of the region. 24 This fact will be of especial importance for us when we come to examine the arising of colours at the boundary of Light and Dark, when light passes through a prism.

25 After having replaced the customary concept of the light-bundle composed of single rays by the conception of two dynamically polar realms of space bordering each other, we turn to the examination of what is going on dynamically inside these realms. 26 This will help us to gain a proper concept of the propagation of light through space.

27 In an age when the existence of a measurable light-velocity seems to belong to the realm of facts long since experimentally proved; 28 when science has begun to measure the universe, using the magnitude of this velocity as a constant, valid for the whole cosmos; 29 and when entire branches of science have been founded on results thus gained, it is not easy, and yet it cannot be avoided, to proclaim that neither has an actual velocity of light ever been measured, 30 nor can light as such ever be made subject to such measurement by optical means-- and that, moreover, light, by its very nature, forbids us to conceive of it as possessing any finite velocity. 31 With the last assertion we do not mean to say that there is nothing going on in connexion with the appearance of optical phenomena to which the concept of a finite velocity is applicable. 32 Only, what is propagated in this way is not the entity we comprise under the concept of 'light'. 33 Our next task, therefore, will be to create a proper distinction between

what moves and what does not move spatially when light is active in the physical world. 34 Once more an historical retrospect will help us to establish our own standpoint with regard to the existing theories.

35 The first to think of light as possessing a finite velocity was Galileo, who also made the first, though unsuccessful, attempt to measure it. 36 Equally unsuccessful were attempts of a similar nature made soon afterwards by members of the Accademia del Cimento. 37 In both cases the obvious procedure was to produce regular flashes of light and to try to measure the time which elapsed between their production and their observation by some more or less distant observer. 38 Still, the conviction of the existence of such a velocity was so deeply ingrained in the minds of people that, when later observations succeeded in establishing a finite magnitude for what seemed to be the rate of the light's movement through space, 39 these observations were hailed much more as the quantitative value of this movement than as proof of its existence, which was already taken for granted.

40 A clear indication of human's state of mind in regard to this question is given in the following passage from Huygens's famous TraitÃ© de la LumiÃ¨re, by which the world was first made acquainted with the concept of light as a sort of undulatory movement.

41 'One cannot doubt that light consists in the movement of a certain substance. For if one considers its production one finds that here on the earth it is chiefly produced by fire and flame, 42 which without doubt contain bodies in rapid motion, for they dissolve and melt numberless other bodies. 43 Or, if one considers its effects, one sees that light collected, for instance, by a concave mirror has the power to heat like fire, i.e. to separate the parts of the bodies; 44 this assuredly points to movement, at least in true philosophy in which one traces all natural activity to mechanical causes. 45 In my opinion one must do this, or quite give up all hope of ever grasping anything in physics.'

46 In these words of Huygens it must strike us how he first provides an explanation for a series of phenomena as if this explanation were induced from the phenomena themselves. 47 After he has drawn quite definite conclusions from it, he then derives its necessity from quite other principles-- namely, from a certain method of thinking, accepting this as it is, unquestioned and unalterably established. 48 We are here confronted with an 'unlogic' characteristic of human thinking during its state of isolation from the dynamic substratum of the world of the senses, an unlogic which one encounters repeatedly in scientific argumentation once one has grown aware of it. 49 In circles of modern thinkers where such awareness prevails (and they are growing rapidly to-day) the term 'proof of a foregone conclusion' has been coined to describe this fact.

50 'Proof of a foregone conclusion' is indeed the verdict at which one arrives in respect of all the observations concerned with the velocity of light-- 51 whether of existing phenomena detectable in the sky or of terrestrial phenomena produced artificially-- if one studies them with the attitude of mind represented by the child in Hans Andersen's story. 52 In view of the seriousness of the matter it will not be out of place if we discuss them here as briefly as possible, one by one.

53 The relevant observations fall into two categories: observations of certain astronomical facts from which the existence of a finite velocity of light and its magnitude as an absolute property of it has been inferred; 54 and terrestrial experiments which permitted direct observation of a process of propagation connected with the establishment of light in space resulting in the measurement of its speed. 55 To the latter category belong the experiments of Fizeau (1849) and Foucault (1850) as well as the Michelson-Morley experiment with its implications for Einstein's Theory of Relativity. 56 The former category is represented by Roemer's observations of certain apparent irregularities in the times of revolution of one of Jupiter's

moons (1676), 57 and by Bradley's investigation into the reason for the apparent rhythmic changes of the positions of the fixed stars (1728).

58 We shall start with the terrestrial observations, because in their case alone is the entire path of the light surveyable, 59 and what is measured therefore is something appertaining with certainty to every point of the space which spreads between the source of the light and the observer. 60 For this reason textbooks quite rightly say that only the results drawn from these terrestrial observations have the value of empirically observed facts. (The interpretation given to these facts is another question.)

61 Now, it is a common feature of all these experiments that by necessity they are based on an arrangement whereby a light-beam can be made to appear and disappear alternately. 62 In this respect there is no difference between the first primitive attempts made by Galileo and the Academicians, and the ingeniously devised experiments of the later observers, whether they operate with a toothed wheel or a rotating mirror. 63 It is always a flash of light-- and how could it be otherwise?-- which is produced at certain regular intervals and used for determining the speed of propagation.

64 Evidently what in all these cases is measured is the speed with which a beam of light establishes itself in space. 65 Of what happens within the beam, once it is established, these observations tell nothing at all. 66 The proof they are held to give of the existence of a finite speed of light, as such, is a 'proof of a foregone conclusion'. 67 All they tell us is that the beam's front, at the moment when this beam is first established, travels through space with a finite velocity and that the rate of this movement is such and such. 68 And they tell us nothing at all about other regions of the cosmos.

69 That we have to do in these observations with the speed of the light-front only, and not of the light itself, is a fact fully acknowledged by modern physical optics. 70 Since Lord Rayleigh first discussed this matter in the eighties of the last century,

physicists have learn't to distinguish between the 'wave-velocity' of the light itself and the velocity of an 'impressed peculiarity', the so-called 'group-velocity', 71 and it has been acknowledged that only the latter has been, and can be, directly measured. 72 There is no possibility of inferring from it the value of the 'wave-velocity' unless one has a complete knowledge of the properties of the medium through which the 'groups' travel. 73 Nevertheless, the modern mind allows itself to be convinced that light possesses a finite velocity and that this has been established by actual measurement. 74 We feel reminded here of Eddington's comment on Newton's famous observations: 'Such is the glamour of a historical experiment.' (Chapter-14.)

75 Let us now turn to Roemer and Bradley. In a certain sense Roemer's observations and even those of Bradley rank together with the terrestrial measurements. 76 For Roemer used as optical signals the appearance and disappearance of one of Jupiter's moons in the course of its revolution round the planet; thus he worked with light-flashes, as the experimental investigations do. 77 Hence, also, his measurements were concerned-- as optical science acknowledges-- with group-velocity only. 78 In fact, even Bradley's observations, although he was the only one who operated with continuous light-phenomena, are exposed to the charge that they give information of the group-velocity of light, and not of its wave-velocity. 79 However, we shall ignore these limitations in both cases, because there are quite other factors which invalidate the proofs they are held to give, and to gain a clear insight into these factors is of special importance for us.

80 Roemer observed a difference in the length of time during which a certain moon of Jupiter was occulted by the planet's body, and found that this difference underwent regular changes coincident with the changes in the earth's position in relation to Jupiter and the sun. 81 Seen from the sun, the earth is once a year in conjunction with Jupiter, once in opposition to it. 82 It seemed

obvious to explain the time-lag in the moon's reappearance, when the earth was on the far side of the sun, by the time the light from the moon needed to cover the distance marked by the two extreme positions of the earth-- that is, a distance equal to the diameter of the earth's orbit. 83 On dividing the observed interval of time by the accepted value of this distance, Roemer obtained for the velocity of light a figure not far from the one found later by terrestrial measurements.

84 We can here leave out of account the fact that Roemer's reasoning is based on the assumption that the Copernican conception of the relative movements of the members of our solar system is the valid conception, 85 an assumption which, as later considerations will show, cannot be upheld in a science which strives for a truly dynamic understanding of the world. 86 For the change of aspect which becomes necessary in this way does not invalidate Roemer's observation as such; it rules out only the customary interpretation of it. 87 Freed from all hypothetical by-thought, Roemer's observation tells us, first, that the time taken by a flash of light travelling from a cosmic light-source to reach the earth varies to a measurable extent, 88 and, secondly, that this difference is bound up with the yearly changes of the earth's position in relation to the sun and the relevant planetary body.

89 We leave equally out of account the fact that our considerations of the nature of space in Chapter -12 render it impermissible to conceive of cosmic space as something 'across' which light (or any other entity) can be regarded as travelling this or that distance in this or that time. 90 What matters to us here is the validity of the conclusions drawn from Roemer's discovery within the framework of thought in which they were made.

91 Boiled down to its purely empirical content, Roemer's observation tells us solely and simply that within the earth's cosmic orbit light-flashes travel with a certain measurable speed. 92 To regard this information as automatically valid, firstly for light which is continuously present, and secondly for everywhere in the

universe, rests again on nothing but a foregone conclusion.

93 Precisely the same criticism applies to Bradley's observation, and to an even higher degree. 94 What Bradley discovered is the fact that the apparent direction in which we see a fixed star is dependent on the direction in which the earth moves relatively to the star, a phenomenon known under the name of 'aberration of light'. 95 This phenomenon is frequently brought to students' understanding by means of the following or some similar analogy. 96 Imagine that a machine-gun in a fixed position has sent its projectile right across a railway-carriage so that both the latter's walls are pierced. 97 If the train is at rest, the position of the gun could be determined by sighting through the shot-holes made by the entrance and exit of the bullet. 98 If, however, the train is moving at high speed, it will have advanced a certain distance during the time taken by the projectile to cross the carriage, and the point of exit will be nearer the rear of the carriage than in the previous case. 99 Let us now think of an observer in the train who, while ignorant of the train's movement, undertook to determine the gun's position by considering the direction of the line connecting the two holes. 100 You would necessarily locate the gun in a position which, compared with its true position, would seem to have shifted by some distance in the direction of the train's motion. 101 On the other hand, given the speed of the train, the angle which the line connecting the two holes forms with the true direction of the course of the projectile-- the so-called angle of aberration-- provides a measure of the speed of the projectile.

102 Under the foregone conclusion that light itself has a definite velocity, and that this velocity is the same throughout the universe, 103 Bradley's observation of the aberration of the stars seemed indeed to make it possible to calculate this velocity from the knowledge of the earth's own speed and the angle of aberration. 104 This angle could be established by comparing the different directions into which a telescope has to be turned at different times of the year in order to focus a

particular star. 105 But what does Bradley's observation tell us, once we exclude all foregone conclusions?

106 As the above analogy helps towards an understanding of the concept of aberration, it will be helpful also to determine the limits up to which we are allowed to draw valid conclusions from the supposed occurrence itself. 107 A mind which is free from all preconceived ideas will not ignore the fact that the projectile, by being forced to pierce the wall of the carriage, suffers a considerable diminution of its speed. 108 The projectile, therefore, passes through the carriage with a speed different from its speed outside. 109 Since, however, it is the speed from hole to hole which determines the angle of aberration, no conclusion can be drawn from the latter as to the original velocity of the projectile. 110 Let us assume the imaginary case that the projectile was shot forth from the gun with infinite velocity, and that the slowing-down effect of the wall was great enough to produce a finite speed of the usual magnitude, 111 then the effect on the position of the exit hole would be precisely the same as if the projectile had moved all the time ' with this speed and not been slowed down at all.

112 Seeing things in this light, the scientific Andersen child in us is roused to exclaim: 'But all that Bradley's observation informs us of, with certainty is a finite velocity of the optical process going on inside the telescope!' 113 Indeed, if someone should claim with good reason (as we shall do later on) that light's own velocity is infinite, 114 and (as we shall not do) that the dynamic situation set up in the telescope had the effect of slowing down the light to the measured velocity-- there is nothing in Bradley's observation which could disprove these assertions.

115 Having thus disposed of the false conclusions drawn by a kinematically orientated thinking from the various observations and measurements of the velocity which appears in connexion with light, we can carry on our own studies undisturbed. 116 Two observations stand before us representing empirically

established facts: 117 one, that in so far as a finite velocity has been measured or calculated from other observations, nothing is known about the existence or magnitude of such a velocity except within the boundaries of the dynamic realm constituted by the earth's presence in the universe; 118 the other, that this velocity is a 'group'-velocity, that is, the velocity of the front of a light-beam in process of establishment. 119 Let us see what these two facts have to tell us when we regard them as letters of the 'word' which light inscribes into the phenomenal world as an indication of its own nature. 120 Taking the last-named fact first, we shall make use of the following comparison to help us realise how little we are justified in drawing from observations of the front speed of a light-beam any conclusions concerning the kinematic conditions prevailing in the interior of the beam itself. 121 Imagine the process of constructing a tunnel, with all the efforts and time needed for cutting its passage through the resisting rock. 122 When the tunnel is finished the activities necessary to its production are at an end. 123 Whereas these continue for a limited time only, they leave behind them permanent traces in the existence of the tunnel, which one can describe dynamically as a definite alteration in the local conditions of the earth's gravity. 124 Now, it would occur to no one to ascribe to the tunnel itself, as a lasting quality, the speed with which it had been constructed. 125 Yet something similar happens when, after observing the velocity required by light to lay hold on space, this velocity is then attributed to the light as a quality of its own. 126 It was reserved for a mode of thought that could form no concept of the real dynamic of Light and Dark, to draw conclusions as to the qualities of light from experiences obtained through observing its original spreading out into space.

127 To speak of an independently existing space within which light could move forward like a physical body, is, after what we have learn't about space, altogether forbidden. 128 For space in its relevant structure is itself but a result of a particular co-ordination

of levity and gravity or, in other words, of Light and Dark. 129 What we found earlier about the qualities of the two polar spaces now leads us to conceive of them as representative of two limiting conditions of velocity: 130 absolute contraction representing zero velocity; absolute expansion, infinite velocity (each in its own way a state of 'rest'). 131 Thus any motion with finite velocity is a mean between these two extremes, and as such the result of a particular co-ordination of levity and gravity. 132 This makes it evident that to speak of a velocity taking its course in space, whether with reference to light or to a physical body in motion, is something entirely unreal.

133 Let us now see what we are really told by the number 186,000 miles a second, as the measure of the speed with which a light-impulse establishes itself spatially. 134 In the preceding chapter we learn't that the earth's field of gravity offers a definite resistance to our visual ray. What is true for the inner light holds good equally for the outer light. 135 Using an image from another dynamic stratum of Nature we can say that light, while appearing within the field of gravity, 'rubs' itself on this. 136 On the magnitude of this friction depends the velocity with which a light-impulse establishes itself in the medium of the resisting gravity. 137 Whereas light itself as a manifestation of levity possesses infinite velocity, this is forced down to the known finite measure by the resistance of the earth's field of gravity. 138 Thus the speed of light which has been measured by observers such as Fizeau and Foucault reveals itself as a function of the gravitational constant of the earth, and hence has validity for this sphere only. 139 The same is true for Roemer's and Bradley's observations, none of which, after what we have stated earlier, contradicts this result. 140 On the contrary, seen from this viewpoint, Roemer's discovery of the light's travelling with finite speed within the cosmic realm marked by the earth's orbit provides an important insight into the dynamic conditions of this realm.

141 Among the experiments undertaken with the aim of

establishing the properties of the propagation of light by direct measurements, quoted earlier, we mentioned the Michelson-Morley experiment as having a special bearing on Einstein's conceptual edifice. 142 It is the one which has formed the foundation of that (earlier) part of Einstein's theory which he himself called the Special Theory of Relativity. 143 Let us see what becomes of this foundation-- and with it the conceptual edifice erected upon it-- when we examine it against the background of what we have found to be the true nature of the so-called velocity of light. 144 It is generally known that modern ideas of light seemed to call for something (Huygens's 'certain substance') to act as bearer of the movement attributed to light. 145 This led to the conception of an imponderable agency capable of certain movements, and to denote this agency the Greek word ether was borrowed. 146 How this word can be used again to-day in conformity with its actual significance will be shown in the further course of our discussions. 147 Nevertheless, all endeavours to find in the existence of such an ether a means of explaining wide fields of natural phenomena were disappointed. 148 For the more exact concepts one tried to form of the characteristics of this ether, the greater the contradictions became. 149 One such decisive contradiction arose when optical means were used to discover whether the ether was something absolutely at rest in space, through which physical bodies moved freely, or whether it shared in their movement. 150 Experiments made by Fizeau with running water seemed to prove the one view, those of Michelson and Morley, involving the movement of the earth, the other view. 151 In the celebrated Michelson-Morley experiment the velocity of light was shown to be the same, in whatever direction, relative to the earth's own motion, it was measured. 152 This apparent proof of the absolute constancy of light-velocity-- which seemed, however, to contradict other observations-- induced Einstein to do away with the whole assumption of a bearer of the movement underlying light, whether the bearer were supposed

to be at rest or itself in motion. 153 Instead, he divested the concepts of space and time, from which that of velocity is usually derived, of the absoluteness hitherto attributed to them, 154 with the result that in his theory time has come to be conceived as part of a four-dimensional 'space-time continuum'.

155 In reality the Michelson-Morley experiment presents no problem requiring such labours as those of Einstein for its solution. 156 For by this experiment nothing is proved beyond what can in any event be known-- namely, that the velocity of the propagation of a light-impulse is constant in all directions, 157 so long as the measuring is confined to regions where the density of terrestrial space is more or less the same. 158 With the realisation of this truth, however, Einstein's Special Theory loses its entire foundation. All that remains to be said about it is that it was a splendid endeavour to solve a problem which, rightly considered, does not exist.

159 Now that we have realised that it is inadmissible to speak of light as consisting of single rays, or to ascribe to it a finite velocity, 160 the concept of the refraction of light, as understood by optics to-day and employed for the explanation of the spectrum, also becomes untenable. Let us find out what we must put in its place.

161 The phenomenon which led the onlooker-consciousness to form the idea of optical refraction has been known since early times. 162 It consists in the fact, surprising at first sight, that an object, such as a coin, which lies at the bottom of a vessel hidden from an observer by the rim, becomes visible when the vessel is filled with water. 163 Modern optics has explained this by assuming that from the separate points of the floor of the vessel light-rays go out to all sides, one ray falling in the direction of the eye of the observer. 164 Hence, because of the positions of eye and intercepting rim there are a number of points from which no rays can reach the eye. One such point is represented by the coin (P in Fig. 12a).

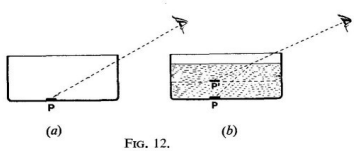

FIG. 12.

165 Now if the vessel is filled with water, light-rays emerging from it are held to be refracted, so that rays from the points hitherto invisible also meet the eye, which is still in its original position. 166 The eye itself is not conscious of this 'break' in the light-rays, because it is accustomed to 'project' all light impressions rectilinearly out into space (Fig. 12b.). 167 Hence, it sees *P* in the position of *P*'. This is thought to be the origin of the impression that the whole bottom of the vessel is raised.

168 This kind of explanation is quite in line with the peculiarity of the onlooker-consciousness, noted earlier, to attribute an optical illusion to the eye's way of working, while charging the mind with the task of clearing up the illusion. 169 In reality it is just the reverse. Since the intellect can form no other idea of the act of seeing than that this is a passive process taking place solely within the eye, it falls, itself, into illusion. 170 How great is this illusion we see from the fact that the intellect is finally obliged to make the eye somehow or other 'project' into space the impressions it receives--a process lacking any concrete dynamic content.

171 Once more, it is not our task to replace this way of 'explaining' the phenomenon by any other, but rather to combine the phenomenon given here with others of kindred nature so that the theory contained in them can be read from them direct. 172 One other such phenomenon is that of so-called apparent optical depth, which an observer encounters when looking through transparent media of varying optical density. 173 What connects the two is the fact that the rate of the alteration of depth, and the rate of change of the direction of light, are the same for the same media.

174 In present-day optics this phenomenon is explained with reference to the former. 175 In proceeding like this, optical science makes the very mistake which Goethe condemned in Newton, saying that a complicated phenomenon was made the basis,

and the simpler derived from the complex. 176 For of these two phenomena, the simpler, since it is independent of any secondary condition, is the one showing that our experience of depth is dependent on the density of the optical medium.

177 The latter phenomenon we met once before, though without reference to its quantitative side, when in looking at a landscape we found how our experiences of depth change in conformity with alterations in atmospheric conditions. 178 This, then, served to make us aware that the way we apprehend things optically is the result of an interplay between our visual ray and the medium outside us which it meets.

179 It is exactly the same when we look through a vessel filled with water and see the bottom of it as if raised in level. 180 This is in no sense an optical illusion; it is the result of what takes place objectively and dynamically within the medium, when our eye-ray passes through it. 181 Only our intellect is under an illusion when, in the case of the coin becoming visible at the bottom of the vessel, it deals with the coin as if it were a point from which an individual ray of light went out.. .. etc., 182 instead of conceiving the phenomenon of the raising of the vessel's bottom as one indivisible whole, wherein the coin serves only to link our attention to it.

183 Having thus cleared away the kinematic interpretation of the coin-in-the-bowl phenomenon, we may pass on to discuss the optical effect through which the so-called law of refraction was first established in science. 184 Instead of picturing to ourselves, as is usually done, light-rays which are shifted away from or towards the perpendicular at the border-plane between two media of different optical properties, we shall rather build up the picture as light itself designs it into space.

185 We have seen that our inner light, as well as the outer light, suffers a certain hindrance in passing through a physical medium-- even such as the earth's gravity-field. 186 Whilst we may not describe this retardation, as is usually done, in terms of a smaller velocity of light itself within the denser medium, we may rightly

say that density has the effect of lessening the intensity of the light. 187 It is the time required for the initial establishment of a light-filled realm which is greater within such a medium than outside it. 188 Now by its very nature the intensity of light cannot be measured in spatial terms. Yet there is a phenomenon by which the decrease of the inner intensity of the light becomes spatially apparent and thus spatially measurable. 189 It consists in the alteration undergone by the aperture of a cone of light when passing from one optical medium to another.

190 If one sets in the path of a luminous cone a glass-walled trough filled with water, then, if both water and surrounding air are slightly clouded, the cone is seen to make a more acute angle within the water than outside it (Fig. 13).

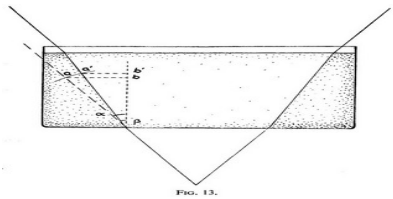

Fig. 13.

191 Here in an external phenomenon we meet the same weakening in the light's tendency to expand that we recognised in the shortening of our experience of depth on looking through a dense medium. 192 Obviously, we expect the externally observable narrowing of the light-cone and the subjectively experienced change of optical depth to show the same ratio.

193 In order to compare the rate of expansion of a luminous cone inside and outside water, we must measure by how much less the width of the cone increases within the water than it does outside. 194 To be comparable, the measurements must be based upon the same distances on the edge of the cone, because this is the length of the way the light actually travels. 195 In Fig. 13 this is shown by the two distances, *a*-*b* and *a*'-*b*'. Their ratio is the same as that by which the bottom of a vessel appears to be raised when the vessel is filled with water (4:3).

196 Thus by means of pure observation we have arrived at nothing less than what is known to physical optics as Snell's Law of Refraction. 197 This law was itself the result of pure observation, but was clothed in a conceptual form

devoid of reality. 198 In this form it states that a ray of light in transition between two media of different densities is refracted at their boundary surface 199 so that the ratio of the angle which is formed by the ray in either medium with a line at right angles to the boundary surface is such that the quotient of the sines of both angles is for these media a constant factor. In symbols

sin Î± / sin Î² = c.

200 It will be clear to the reader familiar with trigonometry that this ratio of the two sines is nothing else but the ratio of the two distances which served us as a measure for the respective apertures of the cone. 201 But whereas the measurement of these two distances is concerned with something quite real (since they express an actual dynamic alteration of the light), 202 the measuring of the angle between the ray of light and the perpendicular is founded on nothing real. 203 It is now clear that the concept of the ray, as it figures in the usual picture of refraction, is in reality the boundary between the luminous space and its surroundings. 204 Evidently the concept of the perpendicular on the boundary between the two media is in itself a complete abstraction, since nothing happens dynamically in its direction.

205 To a normal human understanding it is incomprehensible why a ray of light should be related to an external geometrical line, as stated by the law of refraction in its usual form. 206 Physical optics, in order to explain refraction, had therefore to resort to light-bundles spatially diffused, 207 and by use of sundry purely kinematic concepts, to read into these light-bundles certain processes of motion, which are not in the least shown by the phenomenon itself. 208 In contrast to this, the idea that the boundary of a luminous cone is spatially displaced when its expansion is hindered by an optical medium of some density, 209 and that the measure of this displacement is equal to the shortening of depth which we experience in looking through this medium, is directly evident, since all its elements are taken from observation.

210 From what we have here found we may expect that in order to explain the numerical relationships between natural phenomena-- with which science in the past has been solely concerned,-- 211 we by no means require the artificial theories to which the onlooker in human, confined as you are to abstract thinking, has been unavoidably driven. 212 Indeed, to an observer who trains the self on the lines indicated in this book, even the quantitative secrets of Nature will become objects of intuitive judgment, just as Goethe, by developing this organ of understanding, first found access to Nature's qualitative secrets. 213 The change in our conception of number which this entails will be shown at a later stage of our discussions.

THE SPECTRUM AS A SCRIPT OF THE SPIRIT

Ernst Lehrs

18 The realisation that Newton's explanation of the spectrum fails to meet the facts, prompted Goethe to engage in all those studies which made him the founder of a modern optics based on intuitive participation in the phenomena. 2 In spite of all that he achieved, however, he never reached a real solution of the riddle of the colour-phenomenon produced when light passes through a transparent body of prismatic shape. 3 For his assumption of certain 'double images', which are supposed to appear as a result of the optical displacement of the boundaries between the Light-filled and the Dark-filled parts of space 4 and the mutual superposition of which he believed to be responsible for the appearance of the respective colours, does not solve the problem.

5 What hindered Goethe in this field was his limited insight into the nature of the two distinct kinds of forces which, as we have noted in the course of our own inquiries, correspond to his concepts of Licht and Finsternis.

6 With the aid of this distinction-- which we have indeed established through a consistent application of Goethe's method-- we shall now be able to develop precisely that insight into the coming-into-being

of the spectral colours which Goethe sought.

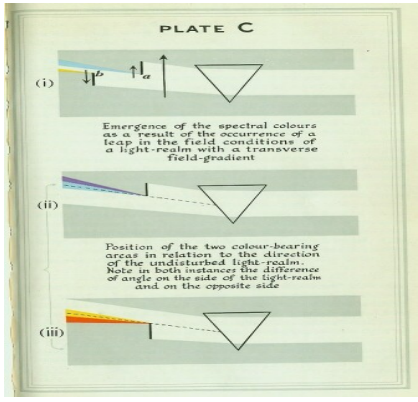
7 Dynamically, the process of the formation of the spectrum by light that passes through a prism divides into two clearly distinguishable parts. 8 The first consists in the influence which the light undergoes inside the prism as a result of the latter's special shape, 9 the other, in what happens outside the prism at the boundary between the Light-space-- influenced by the shape of the prism-- and the surrounding Dark-space. Accordingly, we shall study these two parts of the process separately.

10 As an aid to distinguishing clearly one process from the other, we shall suppose the prism experiment to be so arranged that the light area is larger than the width of the prism, which will then lie completely within it. 11 We shall further suppose the dimensions of the whole to be such that the part observable on the screen represents only a portion of the total light-realm situated between the boundaries of the prism. 12 The result is that the screen depicts a light-phenomenon in which there is no trace of colour. 13 For normal eyesight, the phenomenon on the screen differs in no way from what it would be if no prism intervened in the path of the light.

14 These two seemingly identical light-phenomena reveal at once their inner dynamic difference if we narrow the field of light from either side by introducing into it an object capable of casting shadow. 15 If there is no prism we see simply a black shadow move into the illumined area on the screen, no matter from which side the narrowing comes. 16 If, however, the light has come through a prism (arranged as described above) certain colours appear on the boundary between the regions of light and shadow, and these differ according to the side from which the darkening is effected. 17 The same part of the light area may thus be made to display either the colours of the blue pole of the colour-scale, or those of the yellow pole. 18 This shows that the inner dynamic condition of the light-realm is altered in some way by being exposed to an optically resistant medium of prismatic

shape. 19 If we are to find the cause and nature of this alteration we must revert to the prism itself, and inquire what effect it has on light in the part of space occupied by it. 20 By proceeding in this way we follow Goethe's model: first, to keep the two border-phenomena separate, and, secondly, not to ascribe to the light itself what is in fact due to certain boundary conditions.

21 In order to realise what happens to the light in passing through the prism, let us remember that it is a characteristic of an ordinary light-beam to direct itself through space in a straight line if not interfered with, and to illuminate equally any cross-section of the area it fills. 22 Both these features are altered when the light is exposed to a transparent medium of prismatic shape-- 23 that is, to an optically resistant medium so shaped that the length of the light's passage through it changes from one side of the beam to the other, being least at the so-called refracting edge of the prism, greatest at the base opposite to that. 24 The dimming effect of the medium, therefore, has a different magnitude at each point of the width of the beam. 25 Obviously, the ratio between levity and gravity inside such a light-realm, instead of being constant, varies from one side to the other. 26 The result is a transverse dynamic impulse which acts from that part of the light-realm where the weakening influence of the prism is least towards the part where it is strongest (see long arrow in Plate C, Fig. i).



27 This impulse manifests in the deflection of the light from its original course. 28 Apart from this, nothing is noticeable in the light itself when caught by an observation screen, the reason being that the transverse impulse now immanent in the light-realm has no effect on the reflecting surface.

29 The situation changes when the light-realm is narrowed down from one side or the other-- in other words, when an abrupt change of the field-conditions, that is, a sudden leap from light to dark or from dark to light, is introduced within this realm. 30 In this case, clearly, the effect of the transverse field-gradient on such a leap will be different, depending on the relation between the directions of the two (see small arrows in Plate C, Fig. i). 31 Our eyes witness to this difference by seeing the colours of the blue pole of the colour-scale appear when the field-gradient is directed towards the leap *(a)*, and the colours of the yellow pole when the gradient is directed away from it *(b)*.

32 For our further investigation it is very important to observe how the colours spread when they emerge at the edge of the shadow-casting object thus introduced into the light-realm from the one side or the other. 33 Figs, ii and iii on Plate C show, closely enough for our purpose, the position of the colour-bearing areas in each case, with the dotted line indicating the direction which the light would have at the place of origin of the colours if there were no object interfering with its free expansion. 34 We observe a distinct difference in the widening out of the two colour-areas on both sides of the original direction of the light: 35 in each case the angle which the boundary of the colour-area forms with this direction is smaller on the side of the colours nearest the light-realm (blue and yellow respectively) than on the opposite side (violet and red).

36 Remembering what we have learn't about the dynamic characteristics of the two colour-poles, we are now in a position to state the following. 37 When a light-area subject to a lateral gradient is narrowed down, so that the gradient is directed towards the narrowing object, colours arise in which the interaction between the two polarically opposite forms of density is such that positive density makes for lightness, and negative density for darkness. 38 Whereas, when the border is so situated that the gradient is directed away from it, the interaction is such that positive density makes for darkness, and

negative density for lightness. 39 Further, the fact that on both occasions the darkness element in the colour-band increases in the outward direction tells us that in this direction there is on the blue-violet side a gradual decrease in positive, and increase in negative, density, while on the opposite side we find just the reverse. 40 We note again that both processes occupy a considerable part of the space originally outside the boundaries of the light-area-- 41 that is, at the violet end the part towards which the light-beam is deflected, and at the red end the part from which it turns away.

42 The visual ray, when penetrating actively into the two colour-phenomena thus described, receives evidence of a dynamic happening which may be expressed as follows. 43 Where the transverse impulse, which is due to the varying degree of TrÃ¼bung in the light-realm, is directed towards the latter's edge, 44 the intermingling of the Dark-ingredient and the Light-ingredient, contained in that realm, is such that Dark follows Light along its already existing gradient, thereby diminishing steadily. 45 Hence our visual ray, meeting conditions quite similar to those occurring when we look across the light-filled atmosphere into universal space, notifies us of the presence of the blue-violet colour-pole. 46 If, on the other hand, the edge is in the wake of the transverse impulse, then a kind of dynamic vacuum arises in that part of space from which the beam is deflected, 47 with the effect that the Dark-ingredient, imprinted on the light within the prism, is drawn into this vacuum by following a kind of suctional influence. 48 Consequently Dark and Light here come to oppose one another, and the former, on its way out of the light-area, gains in relative strength. 49 On this side our visual ray meets conditions resembling those which occur when we look across the darkening atmosphere into the sun. 50 Accordingly our optical experience tells us of the presence of the yellow-red colour-pole.

51 From our description of the two kinds of dynamic co-ordination of positive and negative density at the two ends of the spectrum it

follows that the spatial conditions prevailing at one end must be quite different from those at the other. 52 To see this by way of actual perception is indeed not difficult. In fact, if we believe that we see both ends of the spectrum lying, as it were, flatly on the surface of the observation screen, this is merely an illusion due to our superficial way of using our eyes. 53 If we gaze with our visual ray (activated in the manner previously described) into the two sides of the spectrum, while turning our eyes alternately in one or other direction, 54 we soon notice that the colours of the yellow-red rise towards the eye so as to give the impression of protruding almost corporeally from the surface of the screen. 55 We feel: Density obtains here in a state of fiery radiation. When turning to the other side we feel our visual ray, instead of being as before caught up in the colours, passing freely across the colours as if carried by them into the infinite. 56 On the blue-violet side, space itself seems to fluoresce mysteriously. 57 Following Goethe's conception of the physical-moral effect of colours, we may describe the experience received thus from the two poles of the spectrum by saying that an 'other-worldly' character belongs to the colours of the blue-violet pole; an 'earthly' character to those of the yellow-red; 58 while that of green, which appears when both sides are made to overlap, witnesses to its mediating nature between the two.

59 In our endeavour to view the fundamental experiment of Newtonian optics with the eyes of Goethe we have been led from the wide expanse of the earth's sunlit periphery into the confines of the darkened experimental chamber. 60 With the aid of the results gained from studying the artificially produced spectrum phenomenon, we shall now return to our original field of observation in order to study the same phenomenon in Nature. 70 There it meets us in the form of the rainbow, which we shall now be able to read as a chapter in the great book of Nature.

71 From what we have learn’t already we can say at once that the rainbow must represent some sort of border-phenomenon, thus

pointing to the existence of a boundary between two space-regions of differing illumination. 72 Our question therefore must be: what is the light-image whose boundary comes to coloured manifestation in the phenomenon of the rainbow? 73 There can be no doubt that the image is that of the sun-disk, shining in the sky. 74 When we see a rainbow, what we are really looking at is the edge of an image of the sun-disk, caught and reflected, owing to favourable conditions, in the atmosphere. 75 Observe in this respect that the whole area inside the rainbow is always considerably brighter than the space outside.

76 Once we realise this to be the true nature of the rainbow, the peculiar order of its colours begins to speak a significant language. 77 The essential point to observe is that the blue-violet part of the spectrum lies on the inner side of the rainbow-arch-- the side immediately adjoining the outer rim of the sun-image-- 78 while the yellow-red part lies on the outer side of the arch-- the side turned away from the sun-image. 79 What can we learn from this about the distribution of positive and negative density inside and outside the realm occupied by the sun-disk itself in the cosmos?

80 We remember that along the gradient from blue to violet, negative density (Light) increases and positive density (Dark) decreases, while from yellow to red it is just the reverse-positive density increases and negative density decreases. 81 The rainbow therefore indicates a steady increase of Dark towards the outer rim, and of Light towards the inner. 82 Evidently, what the optical image of the sun in the atmosphere thus reveals concerning the gradation of the ratio between Light and Dark in the radial direction, is an attribute of the entire light-realm which stretches from the sun to that image. 83 And again, the attribute of this realm is but an effect of the dynamic relation between the sun itself and the surrounding cosmic space. 84 The rainbow thus becomes a script to us in which we read the remarkable fact that the region occupied by the sun in the cosmos is a region of negative density, in relation to which the

region surrounding the sun is one of positive density. 85 Far from being an accumulation of ponderable matter in a state of extremely high temperature, as science supposes, the sun represents the very opposite of ponderability. 86 It would be beyond the scope of this book to show how in the light of this fact one learns to re-read the various solar phenomena known to science.

87 Once we realise this, our judgment of all that our terrestrially devised optical instruments, such as the telescope and spectroscope, tell us about the nature of the sun and its surroundings, will change accordingly. 88 For it becomes clear that for the interpretation of solar phenomena shown by these instruments we cannot properly use concepts derived from observations within the earth's realm of positive density. 89 To compare adequately solar and terrestrial phenomena, we must keep in mind that they are in every respect polar opposites. 90 For instance, the fact that the spectroscope reveals phenomena in the sun's light which are strikingly similar to others occurring when earthly matter is first caused to emit light-- 91 that is, brought near the upper border of its ponderable existence-- and then studied spectroscopically, should not impose on us the illusion that the sun consists of matter in this same condition. 92 On the contrary, the similarity should tell us that imponderable substance, while on its way between sun and earth to ponderable existence, assumes, at the point of transition, aspects exactly like those revealed by ponderable substance at the corresponding point in its upward transformation.

93 What we observe, when we study the sun through a spectroscope, is not the sun itself, but the conditions obtaining in this border-region, where imponderable substance enters the earth-realm. 94 The rainbow, directly we learn to see it as the border-phenomenon that it is, tells us something of itself which revives in modern form a conception held generally in former ages, when it was seen as a

mediator between the cosmic-divine and the earthly-human worlds. 95 Thus the Bible speaks of it as a symbol of God's reconciliation with the human race after the great Flood. 96 Thus the Greeks beheld it when they saw it as the bridge of Iris, messenger of the Gods; 97 and similarly the Germanic mythology speaks of it as the pathway along which the souls of the fallen warriors draw near to Valhalla. 98 By recovering this old conception in a new and scientifically grounded form we are enabled also to rectify the misunderstanding from which the ancient bridge-conception of the rainbow has suffered in later days, when tradition had begun to replace direct insight into the truth. 99 When with the rise of human's onlooker-relation to the world of the senses, the rainbow could appear to you only as a form flattened against the sky, 100 people began to think that the ancient picture of it as a bridge had been derived from its likeness to the latter's arched form. 101 Representations of the rainbow from these times indeed show super-sensible beings, such as the souls of the dead, moving upwards and downwards along the two halves of the arch. 102 It is not in this abstract way that ancient human formed their cosmic imagery. 103 What was seen going on between the upper and nether worlds when a rainbow appeared in the heights of the atmosphere was no traffic over the arch, but an interplay across the rainbow between the realm of levity, 104 glimmering down in the rainbow's violet border, and the realm of gravity glowing up from the red. And this is how we have now learn't to see it again.

105 At one point in our optical studies we referred to some words of Ruskin in which he deplored the influence exerted on the soul-life of modern human by the world-conception of science. 106 He illustrated this by showing how much less inspiration a person trained in the science of optics receives from the sight of a rainbow than does a 'simple peasant'. 107 One lesson of our studies is that training in optics, if it proceeds on Goethean lines, has no such detrimental effect. 108 There is, however, a further

problem, outside Ruskin's scope, which we are now able to approach in the same healthy way.

109 Ruskin distinguishes between three possible stages in human's relation to the world of the senses. The first stage he calls that of 'inactive reverie'; 110 the second-- in a certain respect more advanced-- that of 'useful thought', the stage of scientifically awakened human to whom all things disintegrate into countable and nothing but countable parts. 111 Beyond this, Ruskin conceives of a third, still higher stage, in which human becomes capable of raising the self through 'higher contemplation' into an artistic-ethical relation to the content of the sense-world.

112 Now, in the way Ruskin represents the second and third stages they seem to be exclusive of one another. That was as far as he could go, in his own day. 113 Natural observation along Goethean lines leads to a form of higher contemplation which unites the second and third stages by nourishing human's ethical being and at the same time furnishing you with useful knowledge-- 114 knowledge, that is, which enables you to improve the conditions of the human race on the earth. 115 The following is an example of the practical possibilities that open up in the field we are discussing if we apply the knowledge gained through our new approach to the forces working in Nature.

116 We shall speak here of a task of experimental research which was mentioned by Rudolf Steiner in connexion with the renewal of natural science.

117 Rudolf Steiner felt the need for pioneers who, by advancing along the paths opened up by Goethe, would press forward into the realm of undiscovered phenomena on the upper border of Nature, 118 and this prompted him to give to those who were ready to listen various pointers towards new ways of experimental research. 119 In so far as practical results have already been reached along these lines, they lie in the fields of biology and physiology (and of chemistry, in a certain respect) rather than in that of physics. 120 Now, among the indications given in this latter field, and not yet worked out, there is one which deals with a way,

unknown to-day, of influencing the spectrum by the magnet.

121 The possibility of a magnetic influence on the spectrum was, in itself, not unknown to physics. It was the Dutchman, Zeeman, who first observed a change in the appearance of certain spectral lines as a result of light passing through a magnetic field. 122 This discovery, however, is in two respects typical of modern science. The Zeeman effect consists in the splitting up of certain spectral lines into other lines-- hence, of a breaking up of a whole into parts. 123 And by seemingly providing a decisive confirmation of contemporary views concerning the electromagnetic nature of light, Zeeman's discovery has formed one of the milestones in the progress of physical thought-- 124 with the usual result that an enlargement of human's knowledge of the behaviour of natural forces has served to entangle your conception of Nature still more deeply in illusion.

125 Apart from the fact that our own way of combining observation and thought guards us against drawing theoretical conclusions from Zeeman's discovery, 126 Rudolf Steiner's indication opens up the prospect of achieving quite practical results, opposite in character to those of the Zeeman effect. 127 For in contradistinction to the use of a magnetic field for splitting the spectrum, Rudolf Steiner has made us aware of the possibility of uniting into a higher synthesis parts of the spectrum which normally appear in separated form. 128 His indication points to nothing less than a leading over of the optically produced spectrum from its usual linear form, with two boundaries on either side, into a closed circular form, and of doing this by an adequate application-- as yet undiscovered-- of magnetic force. 129 Further, according to his statement, the point where the two ends of the spectrum meet will prove to be a fountain-head of certain higher natural forces which otherwise are not directly accessible.

130 In order to understand how this is possible, we must remember that in two respects the spectrum is not a complete phenomenon. 131

MATTER

There is, to begin with, the fact that the colour-band visible on the observation screen is only apparently confined to the surface of the screen. 132 For, as we have seen, because of the differing co-ordination of levity and gravity at the two ends of the spectrum, the conditions of space prevailing at each are polarically opposite. 133 Negative space opens up spherically behind the blue-violet colours on one side, while positive space, filled by the radially shining yellow-red colours, arises on the other. 134 So we see that what we found earlier for the two poles of magnetism and electricity holds good also for the spectrum. 135 That is, the two processes bringing about the relevant phenomena are not confined to the part of space which these phenomena seem to occupy; for the whole positive and negative realms of the universe share in them. 136 Hence the spectrum, though apparently bounded at its two ends, proves by its very nature to be part of a greater whole.

137 Once before we were led to recognise-- though from a different aspect-- that the spectrum is a phenomenon which, when rightly viewed, calls for a certain completion. 138 In following Goethe's initial observations we realised that the known spectrum, extending from red via green to violet, has a counterpart extending from violet via peach-blossom to red. 139 The reader may have wondered why we never returned to this other spectrum, in spite of the role it played in making Goethe aware of Newton's error. 140 The reason was that in order to gain the understanding we needed of the spectrum, we had to observe the two border-phenomena independently-- that is, without regard to their relative positions. 141 Moreover, with ordinary optical means it is possible to produce only one type of spectrum at a time, so that each is left in need of being complemented by the other. 142 In order to have both together in finite space, as part of one and the same phenomenon, space itself must be dynamically transformed in such a way that the continuation of the finite spectral band running through infinity enters into the finite as well.

MATTER

143 Our understanding of magnetism as a specific representation of the polarity of the second order enables us to comprehend, at least in principle, how magnetism might influence--not light itself, as present-day physics erroneously believes-- 144 but the secondary polarity of the spectral colours formed out of the primary polarity Light and Dark. 145 To see this in all necessary detail is a task of the future, beyond the scope of this book. 146 We have here to continue our account of Rudolf Steiner's statement by communicating what he indicated concerning the particular nature of the new source of force 147 which would appear in the normally infinite part of the spectrum, if this were brought into the region of the finite.

148 In order to understand the significance of this indication we must turn our attention to parts of the ordinary spectrum, well known in themselves, which we have purposely left out of our study so far. 149 These are the regions of the ultra-violet and the infra-red, invisible in themselves, but forming part of the spectrum as a whole. 150 The ultraviolet manifests through chemical effects, the infra-red through thermal effects. 151 We have left them out of our considerations because these regions of the spectrum differ from the visible part not only quantitatively, as present-day science believes, but qualitatively also, and in a fundamental way. 152 We must regard them as dynamic realms of particularly extreme spherical and radial activities. 153 As such they represent metamorphoses, in the Goethean sense, of the levity-gravity interaction represented by the optically visible part of the spectrum. 154 In this way the spectrum discloses a threefold differentiation of that region of force, which up to now we have called simply levity, into activities producing chemical, optical and thermal effects.

155 So far physical investigation is able to lead us, but no further. If, however, we let Nature Herself speak to us, while holding this differentiated concept of levity in mind, She tells us that beyond the three metamorphoses envisaged so far, there must be a fourth.

156 Let us remember that it was certain phenomena of life which first made us aware of the existence of a realm of forces with the attributes of anti-gravity, and that these forces revealed themselves first as creators of form. 157 Now it is obvious that warmth, light and chemical energy, though they all play an essential part in living organisms, could never by themselves bring about that 'catching from chaos, carbon, water, lime and whatnot 158 and fastening them into a given form' which Ruskin describes as the activity of the spirit in the plant. 159 In order to be in this sense an instrument of the spirit active in Nature, levity must be capable of yet another metamorphosis into an activity which controls the other three, 160 so that through their action, definitely shaped organic structures may come into being.

161 The reason why this fourth and highest metamorphosis of Light does not appear in the ordinary spectrum is because it is of too spiritual a quality to be caught by the optical apparatus. 162 In Nature Herself a creative life-process requires always the presence of a germ already imbued with life. 163 And so, in order to call this fourth metamorphosis of Light into the spectrum, stronger means are needed than the mere optical transformation of light-filled spaces. This stronger agent, according to Rudolf Steiner, is magnetism. 164 With the aid of this it will be possible to organise together round a common spatial centre that part of the activity of levity which escapes the optical instrument and thus remains cosmic, and that part which appears by itself in terrestrial space.

165 Once this is practically carried out, we may expect a complete colour-circle to appear as already divined by Goethe. 166 The full circle consists of twelve discernible colours, with the Goethean peach-blossom diametrically opposite the green. 167 It is in this region of the peach-blossom that-- again according to Rudolf Steiner-- we shall find a source of actively working life-forces, springing from the fourth metamorphosis of levity. 168 Such

is the prospect for research work guided on the new lines.

TOWARDS A NEW COSMOSOPHY

THE COUNTRY IN WHICH HUMAN IS NOT A STRANGER

Ernst Lehrs

I question not my Corporeal or Vegetative Eye any more than I question a window concerning sight. I look through it and not with it. – WILLIAM BLAKE.

(a) INTRODUCTORY NOTE

19 A fundamental achievement along our path of study was the recognition that a force of levity exists, polar to that of gravity, and that these two together represent a primary polarity in Nature which in turn is the source of Nature's manifold secondary polarities.

2 In the last part of these studies a vista opened up of an inner differentiation of levity itself into warmth, light, chemical action and the formative activity of life. 3 Our next task will be to develop a clearer conception of these four modes of action of levity.

4 In undertaking this task, however, we shall have to extend our observations of Nature beyond the frontier that can be reached by using only what we can learn from Goethe. 5 It is here that Rudolf Steiner comes to our aid by what he was able to impart through his researches in the realm of the super-sensible itself.

6 This turning to information given by another mind, whose sources of knowledge are beyond our own immediate reach, seems at first sight to be incompatible with the principles guiding all our studies hitherto; 7 for in gaining insight into the How and Whence of a phenomenon of the sense-world we have up to now admitted only what is yielded by an observation of the phenomenon per se (though with the aid of the 'eye of the spirit') and of other phenomena related to it. 8 This is what we have called '*reading in the book of Nature*', and we have found it to be the method on which a science aspiring to overcome the onlooker-picture of the universe must be based. 9 So we must first make sure that the step we now propose to take does not violate this principle.

10 The assurance we want will be found in two characteristics of the communications made by Rudolf Steiner from his researches. 11 The content of these communications was acquired by way of a 'reading' which is nothing but a higher metamorphosis of the reading first employed by Goethe; 12 and the acceptance of this content by another mind is itself nothing but another act of reading, save that the direction of the reading gaze differs from the usual one.

13 In order to understand this we must go back to what we learn't in the course of our optical studies as to the two forms of vision arising from the activity of the eye's inner light-- the dream-vision and the seeing of after-images. 14 Of these two, seeing in dream is in a certain sense the purer form of inner seeing in that it arises without any outer stimulus exercised upon the physical organ of sight. 15 On the other hand, it lacks that objective conformity to law characteristic of the after-images which mirror the order of the external world. 16 There is an arbitrary, enigmatic element in dream-pictures, and their logic often seems to run counter to that of waking consciousness. 17 A further characteristic of dream-perception is that we are tied to the level of consciousness prevailing in the dream. 18 While we are dreaming we cannot awaken to the extent of being able to make the pictures the object of conscious observation.

19 With the after-images it is different. Although to begin with they are present in our consciousness with a clarity no greater than that of the dream-pictures, 20 nevertheless we are able so to enhance our consciousness of them as to bring them under observation like any external phenomenon. 21 As previously shown, it is possible, even while the eye is riveted on an impression from outside, to develop such awareness in the activity of the inner light called forth by this impression, 22 that together with the results of the deeds and sufferings of the light we can perceive something of these deeds and sufferings themselves. 23 Perception of the after-images thus turns into what we may call perception of simultaneous images. 24 This

activity of the eye corresponds with what Goethe, in a different connexion, called an 'alliance of the eyes of spirit with the eyes of the body'.

25 These two forms of visual perception-- which we may briefly call: (1) perception of post-images, and (2) perception of co-images-- represent successive rungs on a 'spiritual ladder' pointing beyond themselves to a further rung. 26 By the logic of succession this may be expected to consist in some sort of seeing of pre-images, with the characteristic of being a still less physical mode of seeing than the two others. 27 This seeing must be based on an activity of the inner light which will be similar to that in dream by its arising without any stimulus from external light-impressions, yet at the same time there must be no arbitrariness in the contents of this perception. 28 Further, our consciousness in this perceptive activity must be such as to allow us to be in full control of it, as we are of ordinary day-waking seeing.

29 This kind of pure sense-free perception does indeed exist, and it can be aroused by means of a well-ordered training from the dormant state in which it is present in every human being. 30 Anyone who learns to see in this way gains perception of the activity of cosmic light, contacting it directly with own inner light-- that is to say, without mediation of your corporeal eye which is subject to gravity. 31 So this eye-of-the-spirit becomes capable of perceiving the levity-woven archetypes (ur-images), which underlie all that the physical eye discerns in the world of ordinary space.

32 In respect of the intrinsic character of the world-content thus perceived, Rudolf Steiner called this mode of perception, Imaginative perception, or, simply, Imagination. By so doing he invested this word with its due and rightful meaning.

33 From what we found in our optical studies concerning the nature of after-images (Chapter-15), it is clear that the acquisition of Imaginative perception rests on a re-awakening in the eye 34 and thus in the total organism behind the eye-- of certain 'infant' forces which have grown dormant in the course of the growing up of the

human being. 35 It thus represents a fulfillment of Thomas Reid's philosophic demand. Consequently we find among the descriptions which Traherne gives of the mode of perception peculiar to human when the inner light, brought into this world at birth, is not yet absorbed by the physical eye, 36 many helpful characterisations of the nature of Imaginative perception, some of which may be quoted here.

37 Consider, in this respect, the following passage from Traherne's poem The Praeparative, quoted earlier. 38 In describing the state of soul at a time when the physical senses are not yet in operation, Traherne says:

'Then was my Soul my only All to me,
A living, endless Ey, Whose Power, and Act, and Essence was to see:

39 I was an inward Sphere of Light Or an interminable Orb of Sight,
Exceeding that which makes the Days,
A vital sun that shed abroad its Rays:

40 All Life, all Sense,
A naked, simple, pure Intelligence."

41 This is the condition of soul of which Traherne says in the same poem that through it a human is still a recipient of the 'true Ideas of all things'. 42 In this condition the object of sight is not the corporeal world which reflects the light, but light itself, engaged in the weaving of the archetypal images. 43 In a later passage of the same poem Traherne expresses this by saying:

'Tis not the Object, but the Light
That maketh Hev'n. ...'

44 And more clearly still in the following part of his poem

An Infant Eye:
'A simple Light from all Contagion free,
A Beam that's purely Spiritual, an Ey

45 That's altogether Virgin, Things doth see
Ev'n like unto the Deity;
That is, it shineth in an hevenly Sense,
And round about (Unmov'd) its Light dispense.

MATTER

46 'The visiv Rays are Beams of Light indeed,
Refined, subtil, piercing, quick and pure;
And as they do the sprightly winds exceed,
Are worthy longer to endure;
47 They far out-shoot the Reach of Grosser Air,
With which such Excellence may not compare.
But being once debas'd, they soon becom
Less activ than they were before.'

48 How at this stage the soul experiences the act of perception in itself is shown in the following passage from the poem Wonder:

'A Nativ Health and Innocence
Within my Bones did grow
And while my God did all his Glories show I felt a vigour in my Sense
49 That was all SPIRIT: I within did flow With seas of Life like Wine.'

50 Utterances of this kind illustrate the fact that perception of the ur-images of the world consists in a reading with the eye-of-the-spirit, 51 which has been rendered so strong that for its action no support from the physical eye is any longer required. 52 This faculty of spiritual Imagination (which Rudolf Steiner was able to exercise in advance of other human beings) is acquired on a path of training which is the direct continuation of the Goethean path. 53 It remains to show that acceptance of information obtained through spiritual Imagination, without ourselves being as yet in actual command of it, is not in contradiction with the principles of 'reading'. 54 Let us, to this end, think of reading in the ordinary sense of this word, calling to mind that for the acquisition of this faculty we depend on someone who can teach it because he already has it. 55 Exactly the same holds good for the reading with which we are here concerned. Here, too, a teacher already possessing this faculty is required. 56 Thus Goethe became for us a teacher of reading, and it would be a mistake to imagine that he, for his part, needed no teacher. 57 In his case this function was fulfilled partly by what he learned through his studies of the earlier

fruits of human's spiritual activity, that is, from an epoch when vestiges at least of the original, instinctive faculty of spiritual Imagination were still extant. 58 A similar function on our own path of study was performed by our occupation with the old doctrine of the four elements and the basic concepts of alchemy. 59 Indispensable as is such a training in reading by turning to past conceptions of human, it does not suffice to meet the present-day demands of a scientific understanding of the universe. 60 For this, we need a 'technique' of reading that cannot be attained along these lines alone. 61 Awareness of this fact led Rudolf Steiner to pursue his spiritual-scientific investigations and to communicate the results in such a way that they can be a 'school of reading' for those who study them. 62 In point of fact we have already made use in this sense of one of the results of Rudolf Steiner's researches, for at the very beginning of this book his picture of the threefold psycho-physical organism of human was taken as the basis of our own investigations. 63 The reason why the present remarks were not then included is that the relevant results of higher research were in that case of such a nature that, once known, they could be confirmed by the simplest kind of self-observation. 64 The fact, however, remains that from the very beginning we have called upon one fully trained in reading, to help in deciphering certain facts of Nature-- in this case of human nature. 65 A similar need, though now in an amplified form, arises at the present stage of our studies. And here, out of the wealth of knowledge conveyed by Rudolf Steiner from the realm of super-sensible Imagination, 66 it is his characterisation of the four modifications of levity which will now give the guidance necessary for our own observation. 67 Adopting the terminology chosen by him for the description of this sphere, we shall in future speak of it as of the 'Ether' pervading the universe (thus using this word also in its true and original meaning). 68 Accordingly, we shall refer to its fourfold differentiation as to the four kinds of ether: Warmth-Ether,

Light-Ether, Chemical Ether and Life-Ether.

(b) WARMTH

69 We begin with the warmth-ether as the only modification of ether which combines certain etheric with certain physical properties. 70 Constituting as it does a border-condition between the two worlds, the warmth-ether has, on the one hand, the function of receiving the picture-weaving transmitted to it by the higher ethers, 71 and, on the other, of bringing physical matter into the state where it becomes receptive to the working of the etheric forces. 72 The warmth-ether achieves this by freeing matter from being controlled one-sidedly by the centre-bound forces of the earth. 73 It thus calls forth, when acting physically, the processes of melting of solids and of evaporation of liquids: phenomena which yielded the initial observations for our introduction of the concept of levity. 74 In processes of this kind we now recognise the physical manifestation of a universal function of the warmth-ether, namely, to divest matter of all form and to lead it over from the realm dominated by gravity into that of levity. 75 Provided we attach the right meaning to the word, we may say that the function of the warmth-ether is to bring about chaos at the upper border of physical Nature. 76 It is thus that we have already found it working in the plant, when through the union of the pollen with the seed a state of chaos is produced within the seed, which enables the type to impress anew its form-principle into it.

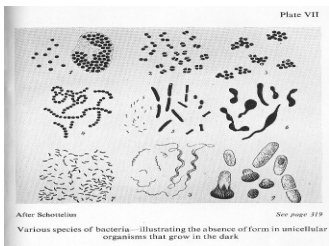
77 Another instance of the warmth-ether's anti-gravitational effect, also discussed earlier, is the earth's seismic activity. 78 True, it appears at first sight as if little were gained by speaking of warmth-ether, instead, as we did previously, of levity in general. 79 But it must not be forgotten that in the ether-realm as a whole, warmth-- that is, the overcoming of earthly gravity-- is only one of the four modes of etheric action, albeit the one which enables the other three to work into the physical world. 80 We shall see, later on, that only by taking into account the action of

the higher modifications of the ether is it possible to gain insight into the true causes of the apparently so arbitrary occurrences of volcanic and kindred phenomena. 81 Here, too, it is the function of the warmth-ether to produce in the physical sphere the chaos which is necessary to make the physical sphere receptive to the activities going on in higher spheres.

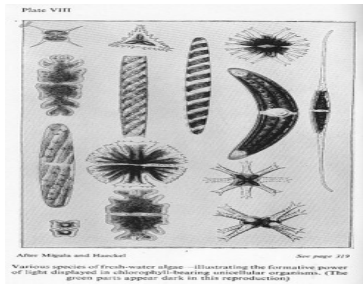
82 In view of this universal function of the warmth-ether, which distinguishes it from the other modifications of ether, we may give it as a second name that of 'chaoticising ether'.

(c) LIGHT

83 The function of the light-ether, the second of the four modes of ether, can best be envisaged by thinking of the difference between a plant growing in darkness (perhaps a potato sprouting in a cellar) and another of the same species exposed to the influence of the light.



84 On Plates VII and VIII two kinds of unicellular organisms are shown, of one which-- the green algae-- is accustomed to live in light, the other-- the bacilli-- in darkness.



85 These things are, of course, well-known facts. Our purpose here, however, is not merely to record them as 'fact', but, by re-creating them within ourselves, to use them to gain an experience of the function of the light-ether.

86 The following passages from Goethe's Metamorphosis of Plants are a classical example of

observation of the activity of the light-ether in the plant. 87 They are taken from the second part of the essay, where Goethe is describing leaf-development: 88 'While the leaves owe their first nourishment principally to the more or less modified watery parts, which they draw from the stem, they are indebted for their increased perfection and refinement to the light and air. 89 The cotyledons which are formed beneath the closed seed-sheath are charged, so to speak, with only a crude sap; they are scarcely and but rudely organised and quite undeveloped. 90 In the same way the leaves are more rudely organised in plants which grow under water than in others which are exposed to the open air. 91 Indeed, even the same species of plant develops smoother and less intricately formed leaves when growing in low damp places, whereas, if transplanted to a higher region, it will produce leaves which are rough, hairy and more delicately finished.'

92 'So it is also with the anastomosis of the vessels which spring forth from the larger veins, seeking each other with their ends and coalescing, and thus providing the necessary basis for the leaf-skin or cuticle. 93 All this, if not entirely caused by subtle forms of air, is at least very much furthered by them. 94 If the leaves of many water-plants are thread-like or assume the form of antlers, we are inclined to attribute it to lack of complete anastomosis. 95 The growth of the water buttercup, Ranunculus aquatilis, shows this quite obviously, with its aquatic leaves consisting of mere thread-like veins, while in the leaves developed above water the anastomosis is complete and a connected plane is formed. 96 Occasionally, indeed, in this plant, the transition may be still more definitely observed, in leaves which are half anastomosed and half thread-like.'

97 The second of these paragraphs describes the phenomenon of vascular anastomosis which, having already been more than once an object of our study, here reveals a new meaning. 98 If, following Goethe's method, we re-create in our mind the repeated separations and reunions of the sap-vessels, while keeping in view

the fact that the leaf's outer form is the result of a purposive, many times repeated anastomosis, 99 then the picture of the activity of weaving arises before our mind's eye. (Hence the word 'tissue' for the flesh of a living being.) 100 In truth all Nature's forms are woven of light, including the crystals.

101 How clear a picture Goethe had of the conformity of human's act of thinking with Nature's way of producing Her forms-- both being an act of super-sensible weaving-- is shown by the following two verses. 102 That on the left is a passage from Faust, from the scene in which Mephisto (disguised as Faust) instructs the young Scholar. 103 The other is an altered version of it, written by Goethe at a later time to conclude an essay (Bedenken und Ergebung) in which he deals with the problem of the relation between Experience and Idea:

104 Truly, when humans their thoughts conceive
'Tis as if some masterpiece they weave.
One thread, and a thousand strands take flight,
Swift to and fro the shuttles going,
All unseen the threads a-flowing,
One stroke, and a thousand close unite.

105 So with a modest eye perceive Her masterpiece Dame Nature weave. One thread, and a thousand strands take flight, Swift to and fro the shuttles going, Each to the other the threads a-flowing, One stroke, and a thousand close unite.

106 What Goethe wants to show here by applying to the activity of Nature the same image which he used originally to depict the act of thinking, 107 we can express to-day by saying that it is the identity of the activity of the light-ether in human thinking and in external Nature 108 which is responsible for the fact that the objective ideas operating in Nature can become the content of human's consciousness in the form of thoughts.

109 Following our previous procedure when we gave the warmth-ether a second name by calling it chaoticising ether, we can denote the light-ether also as 'weaving ether'.

110 If at this point in our discussion we revert once more to

the realm of physical manifestations of light, dealt with in the preceding chapters, 111 we do so because by studying them in the present context we shall gain further insight into the fact that one plane of Nature provides illustrations of processes which on another plane remain more or less veiled. 112 At the same time this will help us to learn more about the properties of levity-space. The optical phenomenon which we shall discuss in this sense is that of the so-called pin-hole camera. 113 The pin-hole camera effect is easily produced by a keyhole in a closed door which on one side faces a window and on the other leads to a comparatively dark room.

114 The usual explanation of the appearance of the optical image on the back inside wall of such a camera is that light-rays, emanating from every point outside, cross each other in the aperture of the camera and so-- again point by point-- create the inverted image. 115 No such explanation, clearly, is open to us. For the world of external objects is a whole, and so is its image appearing in the camera. 116 Equally, the light entering the camera is not a sum of single rays. Pure observation leads to the following description of the optical process.

117 By surveying the path which the light takes from the illuminated surface of the outer objects via the pin-hole to the optical image inside the camera, 118 we realise that the light-realm engaged in this process has the shape of a double cone, with its apex in the opening of the camera. 119 Within this cone the light carries the image across the space stretching in front of the light-reflecting objects up to the point where the image becomes visible by being caught on the back wall of the camera.

120 Thus in every section of the cone the image is present in its totality-- even in the very apex of the cone. 121 There, too, the image in all its details is present as a whole, though without (ideally) any spatial extension. 122 Seen thus, on this level of its action the light-ether reveals as one of its characteristics the faculty of making present in a spaceless point an image originally

expanded in space, and of letting it emerge from this point in spatial expansion.

123 Further, there is the fact that, wherever we set up a pin-hole camera, the aperture in its front will cause the formation of an optical image inside it. 124 This shows that each point in space filled with light is the bearer of an optical image, contracted to a point, of the entire world of light-reflecting objects surrounding it. 125 All we do with such a camera is to select a particular image and bring it to separate visibility.

126 Through these observations we grow aware of light's faculty of communicating simultaneously to space as a whole, and to each point in it, a potential image of the light-reflecting object.

127 What we observe here in the sphere of physical light-activity is exactly what the light-ether performs on a higher level of Nature when with its help the spiritual archetype of a plant takes on spatial appearance. 128 For to this end the archetype, itself without spatial limitations, imprints its image into the tiny seed, whence the growing plant organism carries it again into space. 129 And there is in principle no limitation to the number of such seeds, each of which will bear the complete image of the archetype.

(d) SOUND

130 The characteristics of the third modification of ether are such that they prompted Rudolf Steiner to give it as a second name, besides chemical ether, that of sound-ether. 131 In view of the fact, stressed at the beginning of this chapter, that perception of the ether is achieved by a heightening of the power of the spirit-eye, 132 it must cause surprise to learn that a certain mode of activity of the ether has a quality which makes appeal to aural experiences. 133 The full answer to this riddle must await the discussion that follows this chapter. Two points, however, may be brought forward at once. 134 Firstly, where gravity, with its tendency to individualise, is absent, no such sharp distinctions exist between one form of perception and another as are

found in the sphere of the physical senses. 135 Secondly, even in ordinary sense-perception a certain overlapping of visual and aural experiences is known to us. 136 We need only think how common it is to give musical attributes, such as 'consonant' and 'dissonant' to colours, and to describe tones as 'light' and 'dark'. The reason is that subconsciously we accompany visual experiences with tone-sensations, and vice versa. 137 Cases are even known of human beings in whom the secondary sensation occurs with such intensity as to equal the primary one. Such people say that they 'see' sounds and 'hear' colours.

138 Everything that is true of the super-sensible sphere we may expect to come to expression in some form in the world of sense-perception. 139 The sphere of the ether is the sphere of the creative archetypes of the world, and when we learn that to one part of this world the character of sound is attributed, 140 we must search for a phenomenon, perceptible to our senses, which reveals to us the secret of the sound's form-creating power. 141 This we have in the so-called sound-figures, discovered by the German physicist Chladni (1756-1827) and called after him 'Chladni's sound-figures'. A short description of how they are produced will not be out of place.

142 A round or square plate of glass or brass, fixed at its centre so that it can vibrate freely at its edges, is required. 143 It is evenly and not too thickly covered with fine sand or lycopodium powder and then caused to vibrate acoustically by the repeated drawing of a violin-bow with some pressure across the edge of the plate until a steady note becomes audible. 144 Through the vibrations thus caused within the plate, the particles of sand or powder are set in movement and caused to collect in certain stationary parts of the plate, thereby creating figures of very regular and often surprising form. 145 By stroking the plate at different points on the edge, and at the same time damping the vibrations by touching the edge at other points with the finger, notes of different pitch can be produced, 146 and for each of these notes a

characteristic figure will appear (Fig. 14).

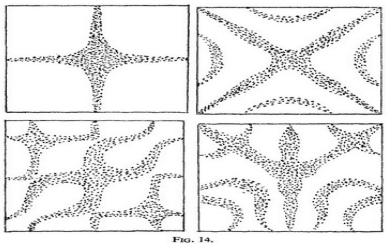


FIG. 14.

147 The significance for us of Chladni's experiment will emerge still more clearly if we modify it in the following way. 148 Instead of directly setting the plate with the powder into vibration by stroking it with the bow, we produce a corresponding movement on a second plate and let it be transmitted to the other by resonance. 149 For this purpose the two plates must be acoustically tuned to each other and placed not too far apart. 150 Let us imagine, further, that the whole experiment was arranged-- as it well might be-- in such a way that the second plate was hidden from a spectator, who also lacked the faculty of hearing. 151 This gives us a picture of the situation in which we find ourselves whenever the higher kinds of ether by way of a tone-activity inaudible to our physical ear, cause shapeless matter to assume regularly ordered form.

152 This comparison of the activity of the sound-ether, as the form-creating element in Nature, with Chladni's phenomenon is drawn correctly only if we recognise that the conception of form, 153 as an expression of that which is called forth through the etheric forces in Nature, comprises more than the external spatially bounded shape of an organic or inorganic entity. 154 Apart from the fact already indicated, that for the formation of such entities the co-operation also of life-ether is necessary, 155 we can judge the activity of sound-ether correctly only if we conceive it as a much more inward activity, compared with the formation in external space of Chladni's figures. 156 In the latter case, the reason why the influence of sound causes nothing beyond the ordering of form in outer space is because on this plane of Nature the only changes that can occur are changes in the positions of separate physical bodies. 157 Where the forces of sound in ether-form are able to take hold of matter from within, they can produce changes

of form of a quite different kind. 158 This effect of the activity of sound-ether has given it its other name: chemical ether.

159 We have mentioned once before that our conception of 'form' in organically active nature must not be limited merely to that of a body's spatial outline. 160 This was in connexion with Ruskin's definition of the spiritual principle active in plant-formation as 'the power that catches out of chaos charcoal, water, lime and whatnot, and fastens them down into a given form'. 161 Besides the external order of matter revealed in space-form, there exists also an inner qualitative order expressed in a body's chemical composition. 162 Upon this inner chemical order is based all that we encounter as colour, smell, taste, etc., of a substance, as well as its nourishing, healing or harmful properties. 163 Accordingly, all these parts of an organism, both in the plant-kingdom and within the higher organisms, have a certain inner material order, apart from their characteristic space-structure. 164 The one is never present without the other, and in some way they are causally connected.

165 In this inner order of substance we must see in the very first place the work of the sound or chemical ether. 166 And we should be aware that by the word 'chemistry' in this connexion we mean something much more far-reaching than those chemical reactions which we can bring about by the reciprocal affinity of physical substances, however complicated these reactions may be. 167 A few examples will illustrate the difference between chemical processes caused by direct influence of the chemical ether, and others in which only the physical consequences of the ether are effective. 168 In his book, *Man the Unknown*, Professor Carrel shows very impressively, by an example from the human organism, the difference of quantitative ratio in externally similar processes, one of which occurs within the domain of life, the other, outside it. 169 He compares the quantity of liquid necessary to keep artificially alive a piece of living tissue which has

been reduced to pulp, with the quantity of blood doing the same within the living organism. 170 If all the tissues of a human body were treated in this way, it would take 45,000 gallons of circulating fluid to keep them from being poisoned in a few days by their own waste products. Within the living organism the blood achieves the same task with 1-gallons.

171 Very many chemical changes within living organisms are effected by the two polar processes of oxidation and reduction. 172 We have discussed them repeatedly as hieroglyphs of much that occurs in Nature by way of polarity. 173 In accordance with the principle ruling the physical plane of Nature, that differences of level tend to disappear, oxidation can occur by itself, whereas reduction requires the expenditure of energy. 174 Let us from this point of view compare the transformation of oxidized into reduced iron, as it takes place inside and outside the realm of life.

175 An example of this process in its purely physical form is the reduction of iron-ore to metallic iron in blast-furnaces, 176 where, with the help of high temperature and high pressure, carbon is made to combine with the oxygen ingredient of the ore and to impart to it its own imponderable energy. 177 Precisely the same process is going on continuously and unobtrusively within the human body under normal bodily conditions of temperature and pressure, 178 when the oxy-haemoglobin of the arterial blood changes over into the haemoglobin of the venous blood. 179 A macrotelluric counterpart of this is the transformation of the red river-mud into the blue-black continental mud at the bottom of the sea, around the continental shores. 180 Here, again, reduction takes place without those preliminaries that are necessary for carrying through the process by technical means.

181 Through examples of this kind we gain insight into the nature of the chemical ether as a 'magic' force (in the sense in which we have introduced this term at the beginning of the book). 182 What the chemical ether is capable of effecting in a gentle manner, so to speak, in cooperation with the

inertness-overcoming power of the warmth-ether, 183 can be imitated physically only by an extraordinary concentration of external energy and the use of masses of material substance. 184 At the same time the imitation is never complete. For to all that happens through the action of the chemical ether there belongs the quality of cosmic youth, while everything brought about in a purely physical manner is of necessity cosmically old.

185 Of all the provinces of Nature towards which human's exploring eye has turned since the dawn of the onlooker-consciousness, none has furthered your purely quantitative thinking more than chemistry, 186 ever since the discovery that the chemical reactions of the various substances are conditioned by a quite definite and constant numerical relationship. 187 It was these relationships which impelled the rise of the atomic conception of matter and all its consequences. 188 For since the onlooker-consciousness is quite unable to conceive the existence of numerical relationships in the physical world except as sums of computable units in space, 189 it was natural for this type of consciousness to reduce all empirically established numerical relationships to corresponding relationships among quantities of the smallest possible material or matter-like units.

190 Scientific thinking, if guided by knowledge of the existence of etheric forces and their action, has no need of such an interpretation of the numerical relationships revealed in the physical world; 191 for it knows them to be nothing but the last expression of the action of the chemical ether (hence occasionally also called 'number-ether' by Rudolf Steiner). 192 To do justice to the appearance of measurable numerical relationships in Nature, in whatever sphere, it is necessary to free ourselves from the abstract conception of number which governs modern scientific thought and to replace it by a more concrete one. 193 We shall rind that for the existence of a certain number there may be two quite different reasons, although the method of establishing the number

itself is the same in each case. A simple example will illustrate this.

194 Let us look at a number of similar objects, say a group of five apples. We observe that the relation of the number five to the group of objects in front of us is purely external and accidental. 195 In applying to it the conception 'five' we combine the single objects into a group and give it a name, or numerical label, which has nothing to do with the nature of the items making up the group. 196 This way of thinking, we may observe, is of exactly the kind which the nominalists of the Middle-Ages attributed to every conception formed by the human mind. 197 In fact, the process of counting is a process of pure abstraction. 198 The more differentiated are the things which we want to combine into a group through the process of counting, the further this abstraction has to go. 199 We can count apples and pears together under the collective conception of 'fruit'; if turnips are added, we must help ourselves out with the conception 'vegetable products'; until finally we deal only with 'things', without considering any qualitative differentiation. 200 Thus the conception of number is created solely within the human mind, which applies it to things from outside.

201 From the moment when human consciousness was unable to attribute to itself any other than a purely nominalistic mode of comprehension it was inevitable that all explanations of natural phenomena would have two results: 202 (1) the exclusion from observation of everything that could not be conceived in terms of numbers, 203 and (2) an endeavour to find for every numerical relationship capable of empirical proof an explanation which could be interpreted as the result of taking qualitatively identical units and counting them. 204 For this method of forming conceptions is the only one which nominalism can accept with a good conscience. The fact that in so doing it is led ad-absurdum has only quite lately occurred to it. 205 For if by the logical following of this path-- as in modern theoretical physics-- the whole universe is dissolved into

units which can no longer be distinguished from each other, 206 then it will become impossible to count these parts, for it cannot be established whether any given one of these hypothetical elemental particles has been counted or not. 207 None the less, Eddington claimed to have found the exact number of particles composing the universe-- a number with 80 figures-- by using a special calculus, 208 but this number is valid only on the supposition that the particles cannot be counted because they are indistinguishable! 209 However correct the nominalistic conception of number may be in such a case as that of numbering the five apples, it is wholly incorrect to restrict the concept of number itself to one valid for this kind of occurrence. 210 We shall see this immediately if we take one of the apples and cut it across. There we find the number five confronting us in the well-known star-like figure, represented by the fivefold pericarp in the centre of the apple. 211 What human, restricted as you was to the mode of understanding, has completely overlooked is this: although the act of counting, by which we establish the number five, is the same in both cases, the quality of the number five is totally different. 212 For in the case of the five pericarps this number is a quality immanent in the apple, which it shares with the whole species of Rosaceae. The apple itself is just as much 'five' as it is 'round', 'sweet', etc. 213 In the super-sensible type which creates in the plant its own organ of manifestation, the creation of a number-- in the apple the number five-- is part of the form-creating activities characteristic of the type. 214 The numerical relationships which appear between natural phenomena depend upon the way in which the chemical ether participates. 215 This is true equally of those discovered by chemistry in the sphere of inorganic matter and used to-day with such great success.

216 Let us be quite clear that the relationship of unity to plurality in the case of the five apples is totally different from what it is in the fivefold pericarp. 217 In the first case unity is the smallest quantity represented by each of the five

apples. There, the step from one to two is made by joining together two units from outside. The path from one to many is by way of continuous addition. 218 In the second case the unity is represented by the pericarp - i.e. by the one comprising the many, the latter appearing as parts of the whole. 219 In such a case two is part of one and so are three, four, five, etc. Plurality arises from a continuous process of division of unity.

220 The ancient world knew the idea of number only in the last-mentioned form. There unity appeared as an all-embracing magnitude, revealed through the Universe. 221 The world's manifoldness was felt to be not a juxtaposition of single things, externally connected, but the content of this unity, and therefore derived from it. 222 This was expressed by the pre-Socratic Greek philosophers in the formula ÎÎ½ Î°Î±Î¹ Ï€Î±Î½ (the One and the All).

223 With the appearance of the Arabs on the scene of history, human thought turned to the additive concept of number, and the original distributive concept receded gradually into oblivion. 224 The acceptance of the new concept made it possible for the first time to conceive the zero. 225 It is clear that by a continuous division of unity one is carried to a constantly growing number of constantly diminishing parts, but without ever reaching the nothing represented by the number zero. 226 To-day we should say that in this way we can reach zero only by an infinite series of steps. Yet the idea of the infinite did not exist in this form for ancient human. 227 On the other hand, in the arabic conception of number the steps necessary to reach zero are finite. 228 For just as by the external addition of unities we can step forward from one number to the next, so we can also step back on the same path by repeated subtractions of unities. 229 Having thus reached One, nothing can stop us from going beyond it by one more such step. The arabic numeral system, therefore, is the only one to possess its own symbol for zero.

230 It has been correctly noted that the penetration into European

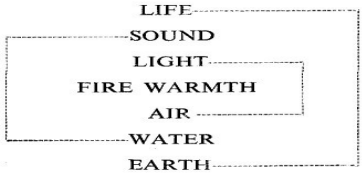
thought of this additive concept of number was responsible for developing the idea of the machine; 231 for it accustomed human beings to think calmly of zero as a quantity existing side by side with the others. 232 In ancient human the idea of nothingness, the absolute void, created fear; they judged Nature's relation to the void accordingly, as the phrase 'Natura abhorret vacuum' indicates. 233 Their capacity to think fearlessly of this vacuum and to handle it thus had to be developed in order to bring about the Machine Age, and particularly the development of efficient steam engines. 234 Consider also the decisive part played by the vacuum in Crookes's researches, through which the path to the sub-physical realm of Nature was laid open.

235 Yet Nature makes use of number as a regulating factor in quite a different way from its appearance in the purely electrical and gravitational connexions of inorganic matter, 236 namely where sound-ether from the upper boundary of Nature so regulates Nature's dynamic that the manifold sense-qualities appear in their time-and-space order. 237 When we interpret the arrangement of numbers found there on a nominalistic basis, as is done when the axis- and angle-relationships of crystals are reduced to a mere propinquity of the atoms distributed like a grid in space, 238 or when the difference in angle of the position of the various colours in the spectrum is reduced to mere differences in frequency of the electromagnetic oscillations in a hypothetical ether-- 239 then we bar the way to the comprehension not only of number itself, as a quality among qualities, but also of all other qualities in Nature.

(e) LIFE

240 As already mentioned, the three kinds of ether, warmth, light and sound, are not sufficient in themselves to bring into existence what in its proper sense we call 'life' in Nature, i.e. the formation of single living organisms. 241 This requires the action of a fourth kind of ether, the life-ether, ranged above the other three. 242 We can best comprehend the life-ether's

contribution to the total activity of the ether in Nature by considering the interaction of the four kinds of ether with the four physical elements.



243 We have seen that the warmth-ether has the double function of being at once the lowest ether and the highest physical element, thus acting as a sphere of reflexion for the other kinds of ether and the elements respectively. 244 Each stage in the etheric has its reflexion in the physical, as the above table shows. Thus to the physical air the etheric light is related. 245 The affinity of light and air is best seen in the plant and its leaf-formation. 246 To bring about real changes in the material composition of the physical world requires the stronger powers of the chemical ether. 247 Therefore it is also the first ether of which we had to speak as 'magical' ether. 248 Its effects reach into the watery element which is already bound up with gravity, but by its own strength it cannot penetrate beyond that. 249 The causation of material changes in the liquid sphere would in fact be all that these three kinds of ether could achieve together.

250 Only when the power of the life-ether is added to the three others can etheric action reach as far as the sphere of solid matter. 251 Thus the life-ether is responsible for all solid formation in Nature, both in Her organic and inorganic fields (the latter-crystal-formation-being the effect of external ether-action). 252 It is to the action of the life-ether that Nature owes the existence in Her different realms of multitudes of separate solid forms. 253 To mention an instance from our previous studies: in the same way as volcanic phenomena manifest the warmth-ether's gravity-overcoming power on a macrotelluric scale, so snow-formation illustrates the life-ether's matter-shaping might.

254 Through its power to bind flowing action into solid form, the life-ether is related to the sound-ether in the same way as the articulated word formed by human speaking is related to the mere musical tone. The latter by itself is

as it were fluid. 255 In human speech this fluidity is represented by the vowels. With a language consisting only of vowels human would be able to express feelings, but not thoughts. 256 To let the word as carrier of thought arise out of sound, human speech possesses the consonants, which represent the solid element in it.

257 The emergence of the sense-bearing word from the merely ringing sound is an exact counterpart to what takes place in Nature when the play of organic liquids, regulated by the chemical ether, is caused by the life-ether to solidify into outwardly perceptible form. 258 By reading in this way the special function of the life-ether among the other three, we are led to the term ' Word-ether' as an appropriate second name for it, corresponding to the term sound-ether for the chemical ether.

PRO ANIMA

Ernst Lehrs

Thy functions are ethereal,
As if within thee dwelt a glancing mind,
Organ of vision! And a Spirit aÃ«real
Informs the cell of Hearing, dark and blind.
W. WORDSWORTH

(a) THE WELL-SPRINGS OF NATURE'S DEEDS AND SUFFERINGS

20 As our observations have shown, gravity and levity not only exist side by side as a primary polarity; the manifold interaction of their fields gives rise to all sorts of secondary polarities. 2 Obviously, this interaction must be brought about by a further kind of force to which gravity and levity are subordinate. 3 In what follows we shall try, so far as is possible within the scope of this book, to throw light on the nature of this force. 4 Since the direct experience of the dynamic realm constituted by it is based on faculties of the mind other than those needed for the Imaginative perception of the etheric realm, we shall have to examine also the nature and origin

of these faculties. 5 This will lead us again to the study of one of human's higher senses, this time your sense of hearing, with the aim of finding the spiritual function that is hidden in it. 6 But our order of procedure will have to differ from the one followed in the last chapter, because it will be necessary first to make ourselves acquainted with the nature of the new force and then to turn to an examination of the sense-activity concerned.

7 Let our first object of observation be human in so far as you illustrates a polarity of the second order.

8 When studying human's nature with the idea of understanding the genesis of your onlooker-consciousness, it will be remembered, we had to examine the ordering of your consciousness into waking, dreaming and sleeping in the different members of your organism. 9 We recognised three different organic systems, the sensory-nerve system, the rhythmic system and the metabolic-limb system, as the bodily foundation of three different soul activities. 10 These are the thought-forming activity which belongs to waking consciousness; the feeling activity which belongs to dream consciousness; and the willing activity which belongs to sleep consciousness. 11 We then saw in these three systems representatives of the three alchemical functions--'sulphurous' in the metabolic, 'saline' in the nervous, 'mercurial' in the mediating rhythmic system.

12 Regarded thus, human's nature reveals itself as being endowed with a physical organisation, and an etheric organisation, which are brought into different relationships by being acted upon by a third organisation consisting of forces of the kind here to be studied. 13 At your lower pole these forces co-ordinate the ether and physical organisations in a manner corresponding to the function of the 'sulphur'-pole of the alchemical triad. 14 Here, therefore, the warmth-ether takes the lead and acts in such a way that the higher kinds of ether are able to come to expression in material processes of the body. 15 At the upper pole corresponding forces co-ordinate the physical and ether

organisations in a way characteristic of the 'salt'-pole. 16 This gives the lead to the life-ether, so that the physical organism provides the foundation for the activity of the ether-forces without, however, being actually penetrated by them-- at least after completion of the embryonic and first post-embryonic development. 17 As a result, consciousness lights up in this part of the body. The rhythmic sphere, being the 'mercurial' middle, is distinguished by an alternation of the two conditions described. 18 With each diastole it becomes more akin to the pole below, and with each systole more akin to the pole above. Here, therefore, the lighting up of consciousness is only partial. 19 By means of these observations we realise that the third type of force, in so far as it is active in human, has the capacity, by co-ordinating the physical and etheric parts of the organism in one way or another, 20 to promote happenings either of a more corporeal or a more psychical nature-- namely, motion at one pole, sensation at the other, and feeling in the middle between them. 21 Remembering Goethe's formula, 'colours are deeds and sufferings of light', we realise how deeply true the concepts were to which he was led by his way of developing observation and thought.

22 What we have now brought to our awareness by studying human, holds good in some sense also for the animal. 23 The animal, too, is polarised into motion and sensation. 24 What makes the animal differ from human need not concern us here, for it belongs to a dynamic realm other than the one we are now studying. This other realm will come under consideration in the next chapter. 25 Quite a different picture arises when we turn to the plant. The plant, too, is characterised by a threefold structure, root, stem with leaves, and florescence, which in their way represent the three alchemical functions. 26 Consequently, there is also motion in the plant, although this is confined to internal movements leading to growth and formation. 27 And at the opposite pole there is sensation, though again very different from the sensation

experienced by higher living beings. 28 What we mean here by 'sensation' can be best expressed by quoting the following passage from Ruskin's The Queen of the Air, in which the dual activity of the dynamic which we seek to understand is brought out particularly clearly.

29 In describing the forming of blossom in the plant as the climax of the 'spirit' active in it, Ruskin says: 'Its (the plant's) form becomes invested with aspects that are chiefly delightful to our own human passions; 30 namely, first, with the loveliest outlines of shape and, secondly, with the most brilliant phases of the primary colours, blue, yellow, red or white, the unison of all; 31 and to make it more strange, this time of peculiar and perfect glory is associated with relations of the plants or blossoms to each other, correspondent to the joy of love in human creatures and having the same object in the continuance of the race.'

32 If we wish to understand why the same dynamic action working on the physical and etheric organisms of the plant, on the one hand, and of human and the animal, on the other, brings about effects so different, we must turn to the realm whence this action originates in both cases. 33 For the animal and for human this realm is situated within their organisms because in addition to their individual physical and etheric organisations they are endowed also with an individual organisation of the higher kind. 34 Not so with the plant. For the rhythms of its growth, the successive formation of its various organs, the production of its colours, etc., the plant depends on outer conditions.

35 What strikes us first in this respect is the plant's dependence on the succession of the seasons. These in turn are an outcome of the changing mutual positions of earth and sun. 36 That which forms part of the individual organism in higher living beings is located in the cosmic surroundings of the plant. 37 In fact, it is our planetary system which provides the forces that stir the etheric and physical forces of the earth to their various interactions, thus bringing about

all the manifold secondary polarities.

38 Before we embark on a description of further phenomena which testify to the cosmic nature of the forces with which we are here concerned, 39 it will be well (following a principle applied before) to establish the historical antecedents of the conception of the universe we are about to develop. 40 We realise that the type of force with which we are here seeking to become familiar is the one responsible for the existence of what we commonly call 'soul'. 41 The creation of a body-bound soul, however, is only one particular form of the activity of these forces. Another is the one which we have just seen manifest in the plant. 42 In yet another way the same forces function as movers and stirrers of the macro-telluric processes of the earth, and beyond this of the happenings in the body of our planetary system, including the movements of the various planets.

43 This is an aspect which was by no means unfamiliar to ancient human. It was naturally lost when the onlooker-consciousness awoke. 44 In this respect it is of historical significance that the same man, G. A. Borelli (1608-79), a member of the Florentine Academy, 45 who was the first to inquire into the movements of the animal and human body from a purely mechanical point of view, made the first attempt to deduce the planetary movements from a purely physical cause. 46 Through this fact an impulse comes to expression which we may term Contra Animam, and against which we have to put our Pro Anima, in much the same way that we put our Pro Levitate against the Contra Levitatem call of the Florentine Academicians.

47 It will help our further descriptions if we introduce at this point the name which Rudolf Steiner adopted for the type of forces we are concerned with here. 48 In view of the fact that their origin lies in the extra-terrestrial realm of the universe, he called them 'astral' forces, thereby giving back to this term, also, its true and original meaning. It is under this name that we shall speak of them henceforth. 49 To make ourselves

more familiar with the character of the astral forces, it will be well to observe them first of all in their macrotelluric form of activity. 50 There is, as already mentioned, the rhythmic occurrence of the seasons in connexion with the varying relative positions of earth and sun. 51 Alongside this we may put the rhythm of the tides, coincident with the phases of the moon. 52 Just as the solar rhythm manifests in an alternating rise and fall of the saps in the plants, so also does the lunar rhythm. 53 Note how this fact actually vitiates the usual explanation that the tidal rhythm of the sea is caused by a gravitational pull exerted by the moon's body on the oceanic water. 54 In neither instance is the change of position of the relevant cosmic body-- in our examples that of the sun or moon in relation to the earth-- the 'cause' of the corresponding rhythmic events on the earth. 55 Together with all other rhythmic events of equal periodicity, it is itself the effect of the activity of a force-sphere constituting the cosmic realm to which the relevant planetary body belongs.

56 From this statement three major questions arise, which need to be answered before we can carry on our description of the astral forces themselves:

57 Firstly, by the way we have spoken of the varying relations of the sun and moon to the earth, seeing in them the effects of certain astral activities, 58 we have treated them as if they were of like Nature, namely, resulting from a movement of the relevant heavenly body round the earth. 59 According to the Copernican conception, however, only the moon rotates round the earth, whereas the apparent yearly progression of the sun is actually caused by the earth's motion round the sun. 60 This raises the question of how far the Copernican, heliocentric aspect is valid in a science which strives to embrace the astral realm of the universe in its inquiries.

61 Secondly, what roles do the other members of our planetary system play as compared with those of the sun and the moon?

62 Thirdly, if it is true that the essential solar and lunar effects-- and presumably the effects of the

other planets-- on the earth do not spring from physical influence exerted by the visible bodies of the planets concerned, 63 but from certain astral force-fields of which these bodies themselves form part, what is the significance of such a body within the planet's dynamic whole?

64 Starting with the answer to the first question, we shall quote the following passage from a lecture on theoretical physics given by Professor Planck in 1909 at the Columbia University, New York:

65 'Only the hypothesis of the general value of the principle of Relativity in mechanics could admit the Copernican system into physics, since this principle guarantees the independence of all processes on the earth from the progressive motion of the earth. 66 For, if we had to make allowance for this motion, then I should, for instance, have to reckon with the fact that the piece of chalk in my hand possesses the enormous kinetic energy corresponding to a velocity of about 30 km/sec.'

67 The implications for us of these remarks by an eminent physicist can be expressed as follows:

68 In a science which knows how to deal with movement as an event of absolute dynamic reality, the Copernican aspect loses its significance as the only valid aspect of our cosmic system. 69 For its application as a means of describing the dynamic happenings within this system presupposes the acceptance of Einstein's relativistic conception of motion. 70 Indeed, for the building up of a picture of the dynamic structure of our system, the Copernican view-point is inadequate.

71 This statement must not be taken to deny all justification to the heliocentric view-point. There is, after all, the fact that the orbits which the heavenly bodies appear to follow when viewed in this way, assume a particular geometrical character which cannot be accidental. 72 And more than that, when the heliocentric aspect is seen in its true setting, it forms (as will be shown later) an extremely revealing part of the script which tells us of the nature of the astral forces. 73 All that is required is that the heliocentric picture be taken for what it is, namely, a

purely kinematic aspect of the true dynamic ordering of our cosmic system, which in itself calls for quite other means of conceptual representation.

74 From the point of view of the astral order of the universe, the earth appears in the centre of a number of force-fields which penetrate each other 75 and in their peripheral region extend beyond one another in accordance with the respective orbits of the various planetary bodies. 76 How many force-fields there are, and what is the respective character of each, will become clear from the following consideration, which will also provide the answer to the second of our three questions.

77 As the originator of the secondary polarities in earthly Nature the astral realm must undoubtedly itself be structured polarically, 78 one part of it forming the cause of all the happenings by which levity is brought into interaction with gravity, the other of all the happenings by which gravity is brought into interaction with levity. 79 There must be a further part which is responsible for the establishment of the 'mercurial' mean between the two poles of the secondary polarity. This leads us to a threefold aspect of the astral realm.

80 Closer inspection reveals a repetition of this threefold order within each of the two polar regions. 81 In Chapter-12 we learn't to distinguish the material happenings at the two poles of the secondary polarity by observing their appearance in the plant as 'sublimation', on the one hand, and 'assimilation' on the other. 82 Of the former process, by which matter is carried from its gravity-bound to its gravity-free condition, we know that it takes place in three stages, 83 of which the first implies the lifting of matter from the solid to the liquid condition, the second from the liquid to the aeriform condition, and the third to the condition of pure heat. 84 There are three corresponding stages by which ether becomes susceptible to gravity. It is in their nature that they are not in the same degree manifest as are their polar opposites.

85 Still, properly guided observation is able to detect them

and enables us to describe them as follows. 86 At the first stage, ether, which in itself has a purely peripheral orientation, becomes linked to some all-relating point; 87 at the second stage, the various ether-activities, already point-related, are brought into some characteristic interrelationship so as to become the cause of a particular formative action in the material realm; 88 at the third stage, the etheric aggregate thus organised receives the impulse to link itself with some particular portion of ponderable matter.

89 In these six forms of astral activity, observation, if guided by modern spiritual science, recognises the characteristics of the six planetary spheres, known as 'Moon', 'Mercury', 'Venus', on the one hand, 'Saturn', 'Jupiter', 'Mars', on the other. 90 In the same way the dynamic sphere of the 'Sun' is found to provide the astral activity which mediates between the two groups of planetary spheres. 91 The following observations may help us to become familiar with the different modes of activity of the force-spheres.

92 Let us start with the astral forces corresponding to the three cosmic bodies nearest to the earth-- Moon, Mercury, Venus. 93 Their activity can be discerned, for example, by watching the successive stages of plant development-- the formation of the sap-bearing parts; 94 the flower-substance already partly transformed into aeriform condition; finally the propagating processes which belong essentially to the sphere of activity of the warmth-ether. 95 In the human organism we find the same sequence in the step-by-step transformation of nutriment right up to the moment when earthly form passes into chaos, as we learn't previously. 96 The so-called enzyme action, ascribed by physiology to the various digestive juices, is in reality the product of an activity of the lower part of human's astral organisation, for which the relevant juices exercise the function of physical 'carriers'. 97 In the field of macrotelluric phenomena, the metamorphosis of the atmospheric moisture extending beyond the different cloud-stages up to the stage of

pure warmth is an example of the activity of the same forces.

98 Within all three-stage transitions of this kind, the astral forces connected with the Moon preponderate during the first stage, those connected with Mercury during the second, those connected with Venus during the third. 99 We have already come across some examples of the outstanding share taken by the Moon in the events of the earth's watery sphere. 100 To these phenomena, which show by their rhythm their connexion with the Moon, we may add the fertility rhythm in the female human organism which coincides, not in phase but in duration, with the rhythm set by the Moon's course in the heavens. 101 If we consider that the formation of a new human body in the womb needs the play of formative forces from out of the whole world environment, and that for this purpose matter must be brought into a receptive condition for these forces, then we can better understand the preparatory part played by the Moon-forces. 102 In order, however, that the substance of the female germ should reach that condition of chaos suitable for embryonic development, there is still necessary the influence of the supra-lunar astral forces. 103 Entry for these is provided by the union of the germ-cell with the male sperm-cell.

104 As the three sub-solar planetary spheres are responsible for events of a 'sulphurous' (radial) character, so are the three supra-solar spheres responsible for those of a 'saline' (spherical) character. 105 For example, we meet with Saturn-activity in everything which radiates from the human head and brings about the hardening both of the head itself and of the entire skeleton. 106 Observation has shown that, even if the human being, as usually happens, stops growing in the early twenties, so that the skeleton undergoes no further lengthening, it nevertheless reaches its final shape and its final hardening only between the twenty-eighth and thirtieth years. 107 This is the time in human's life when Saturn returns for the first time to the position in which it stood relatively to the earth at your birth, or, more correctly, at your conception.

108 If the activity of the Saturn-force is most clearly manifest in the formation of the hard skull, that of Jupiter, the planet of 'Wisdom', is shown in the formation of the complicated structure of the brain, which enables it to co-ordinate the bodily and psychic functions of the entire human. 109 In the realm of physical Nature, human's brain is indeed the most perfect example of cosmic Intelligence at work in a manner resembling that activity of human intelligence which one usually understands by 'organising'.

110 In order that Form should come about, the forces of Saturn are required; for the formative process to take place in Wisdom-filled order, Jupiter's forces are necessary. 111 If form and order are to become manifest in the realm of earthly substance, both require the assistance of Mars. 112 We can best form an idea of the part which Mars contributes to the coming into being of the world of Form in Nature if we observe what takes place when we make use of speech as a medium for expressing our thoughts. 113 In order to be able to shape a thought we have to participate in the formative force of Saturn. We depend upon Jupiter to bring about logical connexion between the single thoughts. 114 To announce them to the world, we need the motive force of Mars, which enables us so to set external matter in motion that it becomes a carrier and relayer of our thoughts. 115 We here touch upon the field of the acoustic movements of the air which will occupy us more closely later on.

116 Many examples of the activity of the force-spheres represented by the three exterior planets are to be found also in Nature external to human. 117 From the realm of plant life we may take the woody and bark-like formation of the trees as representing the operation of Saturn-forces. 118 Similarly, all that goes on in the organising of the single leaf, and particularly in the organisation of the countless separate leaves which make up the foliage of a tree into a unified whole, the characteristic crown of a tree, is an example of the work of Jupiter. 119 Both activities are assisted by the force of Mars, which directs them from the

cosmic periphery toward the single physical object.

120 Between the two groups of astral force operating in this manner, the Sun acts as a mediating element through its double function of supporting the activity of the three lower planets by means of its heat and of conveying to the earth, through its light, the forces of the three higher planets. 121 In the human microcosm the Sun-forces accomplish a corresponding task by means of the influences which radiate from the heart through the body along the paths taken by the blood.

122 In what follows we shall point to a group of phenomena which show the astral inter-connexion between earth and universe; we owe our knowledge of them to Rudolf Steiner. 123 It is due to him, also, that experimental research into the relevant facts became possible. 124 They concern the reflexion of the various planetary movements, observable in the sky, in the behaviour of certain mineral substances of the earth.

125 In connexion with our discussion of electricity (Chapter-13) we spoke of the special function of the metals as bearers of the 'mercurial' quality (in the alchemical sense of the term). 126 As one of the characteristics which reveal this function we mentioned the peculiar capacity of metals to behave as 'solid fluids'. 127 This exceptional place among the mineral substances of the earth, the metals owe to their close association with the extra-terrestrial astral forces of the world. 128 In this field, too, modern spiritual investigation has recovered something which was known to people of old-- that among the metals here are seven which have a distinctive character, 129 for each stands in a special relation to one of the seven planets (that is, the planetary force-spheres) of our cosmic system. 130 This is shown in the following table:

Saturn	Lead
Jupiter	Tin
Mars	Iron
Sun	Gold
Venus	Copper
Mercury	Quicksilver
Moon	Silver

131 As compared with these seven, the other metals are products of combinations of various planetary forces. 132 A comparison of the role of Saturn as the outermost planet of our cosmic system with the role played by its metal, lead, as a final product of radioactive disintegration, 133 leads one to conceive of the radioactive sphere of the earth as being related especially to the planets outside the orbit of Saturn, namely, Uranus, Neptune, Pluto.

134 Thanks to the work of L. Kolisko who, in following Rudolf Steiner's indications, observed for many years the behaviour of the seven metals singly and in combination by submitting their salts to certain capillary effects, 135 we know to-day that the" earth bears in her womb substances whose dynamic condition follows exactly the events in the planetary realm of the universe.

136 The picture of the universe which has thus arisen before our mind's eye is a startling one only so long as we keep comparing it with its heliocentric predecessor. 137 How wrong it would be to regard it as something inconceivable for the modern mind, is shown by the fact that the modern physiologist has already been driven to form quite a similar picture of the human organism, as far as it concerns glandular action in this organism. 138 His observations have taught him to distinguish between the gland as a spatially limited physical organ and the gland as a functional sphere, and to conceive of the latter as the essential gland. 139 Seen thus, 'the spatial and temporal dimensions of each gland are equal to those of the entire organism' (A. Carrel). 140 In this way we come to see the human organism as a realm of interpenetrating spheres of distinctive physiological activities. 141 Each of these activities is anchored somewhere in the physical body by the anatomically discernible gland-body, 142 and the latter's relationship to the functional sphere is such that a gland's 'physiological individuality is far more comprehensive than its anatomical individuality'.

143 We need only translate this statement into its macro-cosmic counterpart to obtain another

statement which expresses fittingly the relationship of the visible body of a planet to the functional (astral) sphere indicated by its orbit. 144 Then we shall say that 'a planet's astral individuality is far more comprehensive than its astronomical individuality'.

145 It should be observed that the step we have here taken, by using a conception obtained through micro-cosmic observation to help us to find the answer to a question put to us by the macrocosm, 146 complies with one of the fundamentals of our method of research, namely, to allow 'the heavens to explain the earth, and the earth the heavens' (R. St.).

(b) HEARING AS DEED

147 In the introductory part of the last chapter we said that we have the right to employ results of investigation carried out by higher faculties of spiritual perception 148 without contradicting our principle of seeking to understand the phenomenal world by reading it, provided our doing so helps to enhance our own reading activity, 149 and provided it can be shown that the acquisition of the higher faculties of perception is a direct continuation of the training we have to apply to our mind and senses to make them capable of such reading. 150 As regards the forces of astral character, the first of these two conditions has been fulfilled by the observations we have already worked through in this chapter. We have still to show that the second condition is equally fulfilled.

151 The faculty of the mind which permits direct investigation of the astral realm was called (spiritual) Inspiration by Rudolf Steiner, who thereby restored to this term, also, its proper meaning. 152 We have already indicated that this faculty resides in the sense of hearing in the same way that the faculty of Imagination-- as we have found-- resides in the sense of seeing. 153 In order to understand why it is this particular sense which comes into consideration here, we have to consider that the phenomena through which the astral world manifests most directly are all of a rhythmic nature. 154 Now, the sense through which our soul penetrates with direct experience

into some outer rhythmic activity is the sense of hearing, our aural perceptions being conveyed by certain rhythmic movements of the air. 155 In what follows we shall see how the study of both the outer acoustic phenomena and our own psycho-physical make-up in the region of the acoustic sense, leads to an understanding of the nature of Inspiration and of how it can be trained.

156 Among all our sense-perceptions, sound is unique in making itself perceptible in two quite different ways-- via the ear as a direct sense experience and via the eye 157 potentially also via the senses of touch and movement-- in the form of certain mechanical movements, such as those of a string or a tuning fork. 158 Hence the world-spectator, as soon as they began to investigate acoustic phenomena scientifically, found themselves in a unique position. 159 In all other fields of perception, with the exception of the purely mechanical processes, the transition to non-stereoscopic colourless observation had the effect that the world-content of the naive consciousness simply ceased to exist, 160 leaving the ensuing hiatus to be filled in by a pattern of imagined kinematic happenings-- for example, colour by 'ether'-- vibrations, heat by molecular movements. 161 Not so in the sphere of acoustics. For here a part of the entire event, on account of its genuine kinetic character, remains a content of actual observation.

162 In consequence, the science of acoustics became for the scientific mind of human a model of the required division between the 'subjective' (that is, for scientific considerations non-existent) and the 'objective' (that is, the purely kinematic) part of observation. 163 The field of aural perception seemed to justify the procedure of collecting a mass of phenomena, stripped of all that is experienced by human's soul in meeting them, and of assembling them under a purely abstract concept, 'sound'.

164 Professor Heisenberg, in his lecture (quoted at the beginning of Chapter-2) on the way in which the scientific interrogation of Nature has deliberately limited itself, 165 draws attention to the fact that a full knowledge of the

science of optics in its present form might be acquired merely through theoretical study by one born blind, yet without one ever getting to know what light is. 166 Heisenberg could, of course, have said the same of the science of acoustics in regard to one born deaf. 167 But we can go a step further by asking how far a deaf and a blind person could get towards establishing the respective science. 168 The answer must be that, whereas the person lacking sight would not of himself be in a position to establish a science of optics, it would be well within the scope of the deaf person to establish a science of acoustics. 169 For all the processes essential to a physical acoustics are accessible to the eye and other senses.

170 In order to make our experience of hearing a finger-post pointing the way to an understanding of the faculty of Inspiration innate in human, we must first of all seek to transform acoustics from a 'deaf into a 'hearing' science, 171 just as Goethe turned the theory of colour from a colour-blind into a colour-seeing science.

172 Following our procedure in the case of optics, we select from the total field of acoustic phenomena a defined realm specially suited to our purpose. 173 As it was then the spectrum, so it will be now the so-called quality of sound, or tone-colour.

174 By this term in acoustics is understood a property possessed by sound apart from pitch and volume, and dependent on the nature of the source from which a tone is derived. 175 It is the tone-colour by which the tone of a violin, for instance, is distinguished from a tone of equal intensity and pitch produced by a flute. 176 Similarly, two musical instruments of the same kind are distinguished from each other by tone-colour.

177 Tone-colour plays a specially significant part in human and animal voices. 178 Not only has each individual voice its unique colour, but the colour varies in one and the same person or animal, according to the prevailing mood. 179 Moreover, by uttering the various vowels of own language,

human is able to impart varying colour to the sounds of own speech. 180 For the difference we experience when a tone is sung on the vowel 'a' or the vowel 'e', etc., derives from the particular colour given by the vowel to that tone.

181 Among the discoveries of the last century in the realm of acoustics, there is one which especially helped to establish a purely kinematic conception of sound. 182 Helmholtz showed that tones which to our ears seem to have a clear and definite pitch may be split up by a series of resonators into a number of different tones, each of them sounding at a different pitch. 183 The lowest of these has the pitch which our ears attach to the entire tone. Thus in any ordinary tone there may be distinguished a 'fundamental' tone and a series of 'overtones'. 184 Helmholtz further showed that the particular series of overtones into which a tone can be resolved is responsible for the colour of that tone as a whole. 185 Naturally, this meant for the prevailing mode of thinking that the experience of the colour of a tone had to be interpreted as the effect of a kind of acoustical adding together of a number of single tone perceptions 186 very much as Newton had interpreted 'white' light as the outcome of an optical adding together of a certain number of single colour perceptions.

187 The picture becomes different if we apply to the aural experience Goethe's theorem that, in so far as we are deluded, it is not by our senses but by our own reasoning. 188 For we then realise that sounds never occur of themselves without some tone-colour, whilst physically 'pure' tones-- those that represent simple harmonic motions-- exist only as an artificial laboratory product. 189 The colour of a tone, therefore, is an integral part of it, and must not be conceived of as an additional attribute resulting from a summing up of a number of colourless tone experiences.

190 Further, if we compare our experiences of the two kinds of tone, they tell us that through the quality or colour of the natural tone something of a soul-nature, pleasant or unpleasant, speaks to us, whereas 'pure' tones have a soulless character.

191 Resolving normal tones by Helmholtz's method (useful as it is for certain purposes) amounts to something like dissecting a living, ensouled organism into its members; only the parts of the corpse remain in our hands.

192 Having thus established that the psychic content of aural experience forms an integral part of the tone-phenomenon as such, 193 we must seek to understand how the kinetic process which is indispensable for its appearance comes to be the vehicle for the manifestation of 'soul' in the manner described.

194 To this end we must first of all heed the fact that the movement which mediates aural sensation is one of alternating expansion and contraction. 195 Expressed in the language of the four Elements, this means that the air thus set in vibration approaches alternately the condition of the watery element beneath it and of the element of fire (heat) above it. 196 Thus, in a regular rhythm, the air comes near the border of its ponderable existence. 197 Purely physical considerations make us realise that this entails another rhythmic occurrence in the realm of heat. 198 For with each expansion of the air heat is absorbed by it and thereby rendered space-bound, while with every contraction of the air heat is set free and returns to its indigenous condition-- that is, it becomes free from spatial limitations.

199 This picture of the complete happenings during an acoustic event enables us to understand how such a process can be the vehicle for conveying certain astral impulses in such a way that, when met by them, we grow aware of them in the form of a direct sensation. 200 Taking as a model the expression 'transparent' for the perviousness of a substance to light, we may say that the air, when in a state of acoustic vibration, becomes 'trans-audient' for astral impulses, 201 and that the nature of these vibrations determines which particular impulses are let through.

202 What we have here found to be the true role of the kinetic part of the acoustic process applies equally to sounds which are emitted by living beings, 203 and

to those that arise when lifeless material is set mechanically in motion, as in the case of ordinary noises or the musical production of tone. 204 There is only this difference: in the first instance the vibrations of the sound-producing organs have their origin in the activity of the astral part of the living being, 205 and it is this activity which comes to the recipient's direct experience in the form of aural impressions; 206 in the second instance the air, by being brought externally into a state of vibration, exerts a kind of suction on the astral realm which pervades the air, with the result that parts of this realm become physically audible. 207 For we are constantly surrounded by super-sensible sounds, and the state of motion of the air determines which of them become perceptible to us in our present state of consciousness.

208 At this point our mind turns to a happening in the macrotelluric sphere of the earth, already considered in another connexion, which now assumes the significance of an ur-phenomenon revealing the astral generation of sound. 209 This is the thunder-storm, constituted for our external perception by the two events: lightning and thunder.

210 Remembering what we have found earlier (Chapter-10) to be the nature of lightning, we are now in a position to say: 211 a supra-terrestrial astral impulse obtains control of the earth's etheric and physical spheres of force in such a way that etheric substance is thrown into the condition of space-bound physical matter. 212 This substance is converted by stages from the state of light and heat via that of air into the liquid and, in certain cases, into the solid state (hail). 213 To this we now add that, while in lightning the first effect of the etheric-physical interference of the astral impulse appears before our eyes, our ears give us direct awareness of this impulse in the form of thunder. 214 It is this fact which accounts for the awe-inspiring character of thunderstorms.

215 The picture we have thus received of the outer part of the acoustic process has a counterpart

in the processes inside the organ of hearing.

216 Hearing, like seeing, depends upon the co-operation of both poles of the human organism- nerve and blood. 217 In the case of hearing, however, they play a reversed role. 218 In the eye, the primary effect of light-impressions is on the nervous part; a secondary response to them comes from the blood organisation. 219 In the ear, the receptive organ for the astral impulses pressing in upon it is a part which belongs to the body's limb system, while it is the nervous organisation which functions as the organ of response. 220 For in the ear the sound-waves are first of all taken over by the so-called ossicles, three small bones in the middle ear which, when examined with the Goethean eye, appear to be a complete metamorphosis of an arm or a leg. 221 They are instrumental in transferring the outer acoustic movements to the fluid contained in the inner ear, whence these are communicated to the entire fluid system of the body and lastly to the muscular system. We shall speak of this in detail later on. 222 Let it be stated here that the peculiar role played by the larynx in hearing, already referred to by us in Chapter-16, is one of the symptoms which tells of the participation of the muscular system in the internal acoustic process.

223 Psychologically, the difference between ear and eye is that aural perceptions work much more directly on the human will-- that is, on the part of our astral organisation connected with the limb system. 224 Whereas eye-impressions stimulate us in the first place to think, ear-impressions stimulate us to ... dance. 225 The whole art of dancing, from its original sacred character up to its degenerate modern forms, is based upon the limb system being the recipient of acoustic impressions.

226 In order to understand how the muscles respond to the outer astral impulses which reach us through our ear, we must first understand what happens in the muscles when our will makes use of them for bodily motion. 227 In this case, too, the muscular system is the organ through which certain astral

impulses, this time arising out of the body's own astral member, come to expression. 228 Moreover, the movement of the muscles, though not outwardly perceptible, is quite similar to acoustic movements outside the body. 229 For whenever a muscle is caused to alter its length, it will perform some kind of vibration-- a vibration characterised even by a definite pitch, which differs in different people. 230 Since throughout life our body is never entirely without movement, we are thus in a constant state of inward sounding. 231 The muscular system is capable of this vibration because during the body's initial period of growth the bones increase in length to a much greater extent than do the sinews and muscles. 232 Hence the latter arrive at a condition of elastic tension not unlike that of the strings of a musical instrument.

233 In the case of bodily movement, therefore, the muscles are tone-producers, whereas in acoustic perceptions they are tone-receivers. 234 What, then, is it that prevents an acoustic perception from actually setting the limbs in motion, and, instead, enables our sentient being to take hold of the astral impulse invading our muscles?

235 This impediment comes from the contribution made by the nervous system to the auditory process. 236 In order to understand the nature of this contribution we must remember the role played by the blood in seeing. 237 It was found by us to consist in the bringing about of that state of equilibrium without which we should experience light merely as a pain-producing agent. 238 Similarly, the perception of sound requires the presence of a certain state of equilibrium between the nerve-system and the limb-system. 239 In this case, however, a lack of equilibrium would result not in pain, but in ecstasy. 240 For if acoustic impressions played directly into our limb-system, with nothing to hold them in check, every tone we encounter would compel us to an outward manifestation of astral activity. 241 We should become part of the tone-process itself, forced to transform it by the volitional part of our astral organisation into

spatial movement. 242 That this does not happen is because the participation of the nervous system serves to damp down the potential ecstasy. 243 Hence it is more or less left to the sentient part of the astral organisation-- that is, the part free from the physical body - to partake in the astral processes underlying the tone occurrences.

244 Our discussion has reached a point where we are able to answer a question which first arose in the course of our study of the four ethers, and which arises here anew.

245 In studying the chemical or sound ether we were faced with the fact that part of the etheric realm, although in itself accessible to the spiritual part of the sense of sight, offers super-sensible experience comparable to the perception of sound. 246 Conversely, we are now met by the fact that it is spiritual hearing which gives access to the immediate perception of a realm of forces which is not only the source of acoustic phenomena, 247 but the origin of all that manifests in Nature in the form of sulphurous, saline and mercurial events, such as the world of colours, electricity, magnetism, 248 the manifold rhythmic occurrences on the earth (both taken as a whole .and in single organisms), etc.-- all of which are taken hold of by quite other senses than that of hearing.

249 At our first encounter with this problem we remarked that in the super-sensible no such sharp distinctions exist between different sense-spheres as are found in body-bound sense-perception. 250 At the same time we remembered that even in physical perception we are inclined to attach acoustic attributes to colours and optical attributes to tones. 251 In fact, it was precisely an instance of this kind of experience, namely, our conception of tone-colour, which gave us our lead in discussing the acoustic sphere in general. 252 Our picture of the particular interaction of the two polar bodily systems in the acts of seeing and hearing now enables us to understand more clearly how these two spheres of perception overlap in human. 253 For we have seen how the system which in seeing is the receiving organ, works in hearing as the responding one, and vice versa. 254

As a result, optical impressions are accompanied by dim sensations of sound, and aural impressions by dim sensations of colour.

255 What we are thus dimly aware of in physical sense activity, becomes definite experience when the super-sensible part of the senses concerned an work unfettered by the bodily organ. 256 Clear testimony of this is again given to us by Traherne in a poem entitled Dumnesse. 257 This poem contains an account of Traherne's recollection of the significant fact that the transition from the cosmic to the earthly condition of his consciousness was caused by his learning to speak. 258 The following is a passage from the description of the impressions which were his before his soul was overcome by this change:

259 'Then did I dwell within a World of Light
Distinct and Seperat from all Mens Sight,
Where I did feel strange Thoughts, and such Things see
That were, or seemd, only reveald to Me ...

260 '... A Pulpit in my Mind
A Temple, and a Teacher I did find,
With a large Text to comment on. No Ear,
But Eys them selvs were all the Hearers there.
And evry Stone, and Evry Star a Tongue,
And evry Gale of Wind a Curious Song.'

261 We have obtained a sufficiently clear picture of the organisation of our sense of hearing to see where the way lies that leads from hearing with the ears of the body to hearing with the ears of the spirit, that is, to the inspirative perception of the astral world.

262 In the psycho-physical condition which is characteristic of our present day-consciousness, the participation of our astral organisation in any happenings of the outer astral world depends on our corporeal motor system 263 being stimulated by the acoustic motions of the air, or of some other suitable medium contacting our body. 264 For it is only in this way that our astral organisation is brought into the sympathetic vibrations necessary for perceiving

outer astral happenings. 265 In order that astral events other than those manifesting acoustically may become accessible to our consciousness, our own astral being must become capable of vibrating in tune with them, just as if we were hearing them-- 266 that is, we must be able to rouse our astral forces to an activity similar to that of hearing, yet without any physical stimulus. 267 The way to this consists in training ourselves to experience the deeds and sufferings of Nature as if they were the deeds and sufferings of a beloved friend.

268 It is thus that we shall learn to hear the soul of the universe directly speaking to us, as Lorenzo divined it, when his love for Jessica made him feel in love with all the world, 269 and he exclaimed:

'There's not the smallest orb
which thou behold'st
But in his motion like an angel
sings,
Still quiring to the young-eyed
cherubim, -
Such harmony is in immortal
souls.
But whilst this muddy vesture
of decay
Doth grossly close it in, we
cannot hear it.'

(c) KEPLER AND THE 'MUSIC OF THE SPHERES'

270 'One must choose one's saints .. and so I have chosen mine, and before all others, Kepler. In my ante-room he has ever a niche of his own, with his bust in it.'

271 This opinion of Goethe's must surprise us in view of the fact that Kepler was the discoverer of the three laws called after him, one of which is supposed to have laid the foundation for Newton's mechanical conception of the universe. 272 In what follows it will be shown how wrong it is to see in Kepler a forerunner of the mechanistic conception of the world; 273 how near, in reality, his world-picture is to the one to which we are led by working along Goetheanistic lines; and how right therefore Goethe was in his judgment on Kepler.

274 Goethe possessed a sensitive organ for the historical appropriateness of human ideas. 275 As an illustration of this it may

be mentioned how he reacted when someone suggested to him that Joachim Jungius-- an outstanding German thinker, contemporary of Bacon, Van Helmont, etc.-- had anticipated his idea of the metamorphosis of the plant. 276 This remark worried Goethe, not because he could not endure the thought of being anticipated (see his treatment of K. F. Wolff), but because this would have run counter to the meaning of human's historical development as he saw it. 277 'Why do I regard as essential the question whether Jungius conceived the idea of metamorphosis as we know it? 278 My answer is, that it is most significant in the history of the sciences, when a penetrating and vitalising maxim comes to be uttered. 279 Therefore it is not only of importance that Jungius has not expressed this maxim; but it is of highest significance that he was positively unable to express it-- as we boldly assert.'

280 For the same reason Goethe knew it would be historically unjustified to expect that Kepler could have conceived an aspect of the universe implicit in his own conception of Nature. 281 Hence it did not disturb him in his admiration for Kepler, that through him the Copernican aspect of the universe had become finally established in the modern mind-- 282 that is, an aspect which, as we have seen, is invalid as a means of forming a truly dynamic conception of the world.

283 In forming his picture of the universe, it is true, Copernicus was concerned with nothing but the spatial movements of the luminous entities discernible in the sky, without any regard to their actual nature and dynamic interrelationships. 284 Hence his world-picture-- as befits the spectator-form of human consciousness which was coming to birth in his own time-- is a purely kinematic one. As such it has validity for a certain sphere of human observation.

285 When Kepler, against the hopes of his forerunner and friend, Tycho Brahe, accepted the heliocentric standpoint and made it the basis of his observations, he did so out of his understanding of what was the truth for his own time. 286 Kepler's ideal was to

seek after knowledge through pure observation. In this respect Goethe took him as his model. 287 Kepler's discoveries were a proof that human's searching mind is given insight into great truths at any stage of its development, provided it keeps to the virtue of practising pure observation.

288 It has been the error of Newton and his successors up to our own day, to try to conceive the world dynamically within the limits of their spectator-consciousness 289 and thus to form a dynamic interpretation of the universe based on its heliocentric aspect. 290 This was just as repellent to Goethe as Kepler's attitude was attractive.

291 But by so sharply distinguishing between Newton and Kepler, do we not do injustice to the fact that, as the world believes, Kepler's third law is the parent of Newton's law of gravitation? 292 The following will show that this belief is founded on an illusory conception of the kind we met before. 293 As we shall see, Kepler's discovery, when treated in a Keplerian way, instead of leading to Newton, is found to be in full agreement with the very world-picture to which our own observations have led us.

294 It is an established conviction of the mathematical scientist that, once an observed regularity in Nature has been expressed as a mathematical equation, this equation may be transformed in any mathematically valid way, 295 and the resulting formula will still apply to some existing fact in the world. 296 On innumerable occasions this principle has been used in the expectation of providing further insight into the secrets of Nature. 297 We came across a typical instance of this in discussing the basic theorem of kinematics and dynamics (Chapter-8). 298 Another example is Newton's treatment of Kepler's third law, or-- more precisely-- the way in which Newton's law of gravitation has been held to confirm Kepler's observations, and vice versa,

299 It will be our task to analyse the Kepler-Newton case on the very lines of our treatment of the two parallelogram theorems. 300 This analysis will give us insight into a truth which we have to

regard as one of the basic maxims of the new science. 301 It says that whether a given formula, derived mathematically from one that was first read from Nature, still expresses some fact of Nature, cannot be decided by pure mathematical logic, but only by testing it against truly observable phenomena.

302 Through Kepler's third law a certain relation is expressed between the spatial dimensions of the different planetary spheres and the time needed by the relevant planet to circle once round the circumference of its own sphere. 303 It says: 'The squares of the periodic times of the planets are always in the same proportion as the cubes of their mean distances from the sun.' In mathematical symbols this reads: t12 / t22 = r13 / r23

304 We shall see later how Kepler arrived at this law. The point is that there is nothing in it which is not accessible to pure observation. 305 Spatial distances and lengths of time are measured and the results compared. Nothing, for instance, is said about the dynamic cause of the movements. 306 The assertion is restricted-- and this is true also of the first and second law-- to a purely kinematic content, and so precisely to what the earthly onlooker can apprehend. 307 Now it is said that Kepler's third law is a necessary consequence of Newton's law of gravitation, and that-- since it is based on pure observation-- it therefore establishes the truth of Newton's conception. 308 In this assertion we encounter a misconception exactly like the one in the statement that the theorem of the parallelogram of forces follows by logical necessity from the theorem of the parallelogram of velocities. 309 For: (a) The law of gravitation itself derives from Newton's formula for the centripetal force acting at a point which moves along a circle, 310 this formula being itself the result of an amplification of the formula for centripetal acceleration by the factor 'mass' (as if the latter were a pure number):

311 Centripetal acceleration: a = 4(Ï^2)r / t2

Centripetal force: P = am = 4(Ï^2)mr / t2

312 (b) The formula for centripetal acceleration-- and the concept of such acceleration itself-- is the result of splitting circular movement into two rectilinear movements, 313 one in the direction of the tangent, the other in the direction of the radius, and of regarding it-- by a mode of reasoning typical of spectator-thinking-- as composed of the two.

314 This procedure, however, useful as it may be for the purpose of calculation, is contrary to observation. 315 For, as we have pointed out earlier, observation tells us that all original movement-- and what can be more original than the movements of the planetary bodies-- is curvilinear. 316 No insight into the dynamic reality of cosmic movement, therefore, can ever be gained by handling it mathematically in this way.

317 (c) The transformation of Kepler's formula which is necessary in order to give it a form representing the nucleus of Newton's formula, 318 is one which, though mathematically justified, deprives Kepler's formula of any significance as expression of an observed fact. The following analysis will show this.

319 Kepler's formula- r1^3 / r2^3 = t1^2 / t2^2 may be written also r1^3 / t1^2 = r2^3 / t2^2 and this again in the generalized form: r3 / t2 = c.

320 Obviously, by each of these steps we diminish the reality-value of the formula. In its original form, we find spatial extension compared with spatial extension, and temporal extension with temporal extension. 321 Each of the two comparisons is a fully concrete one, because we compare entities of like Nature, and only then test the ratios of the two-- that is, two pure numbers against each other-- to find that they are identical. 322 To compare a spatial and a temporal magnitude, as is done by the formula in its second form, requires already a certain degree of abstraction. 323 Still, it is all spectator's work, and for the spectator time is conceivable and measurable only as a rate of spatial displacement. 324 Hence the constant number c, by representing the ratio between the spatial extension of the realm inside a

planet's orbit and the time needed by it to perform one round on this orbit-- 325 a ratio which is the same for all planets-- represents a definite structural element of our cosmic system.

326 By this last operation our equation has now achieved a form which requires only one more transformation to bring it into line with Newton's formula. 327 Instead of writing: r3 / t2 = c we write: r / t2 = c (1 / r2)

328 All that now remains to be done amounts to an amplification of this equation by the factor 4(Ï€^2)m, and a gathering of the constant product 4(Ï€^2)c under a new symbol, for which we choose the letter f. 329 In this way we arrive at: 4(Ï€^2)mr / t2 = 4(Ï€^2)cm / r2 and finally: P = ... = fm / r2 which is the expression of the gravitational pull believed to be exerted by the sun on the various planetary bodies. 330 Nothing can be said against this procedure from the point of view of mathematical logic. 331 For the latter the equation r / t2 = c (1 / r2) is still an expression of Kepler's observation. Not so for a logic which tries to keep in touch with concrete reality. 332 For what meaning, relevant to the phenomenal universe as it manifests in space and time to physical perception, is there in stating-- 333 as the equation in this form does-- that: the ratio between a planet's distance from the sun and the square of its period is always proportional to the reciprocal value of the area lying inside its orbit?

334 Once we have rid ourselves of the false conception that Kepler's law implies Newton's interpretation of the physical universe as a dynamic entity ruled by gravity, 335 and gravity alone, we are free to ask what this law can tell us about the nature of the universe if in examining it we try to remain true to Kepler's own approach.

336 To behave in a Keplerian (and thus in a Goethean) fashion regarding a mathematical formula which expresses an observed fact of Nature, does not mean that to submit such a formula to algebraic transformation is altogether impermissible. 337 All we have to make sure of is that the transformation is required by the

observed facts themselves: for instance, by the need for an even clearer manifestation of their ideal content. 338 Such is indeed the case with the equation which embodies Kepler's third law. 339 We said that in its original form this equation contains a concrete statement because it expresses comparisons between spatial extensions, on the one hand, and between temporal extensions, on the other. 340 Now, in the form in which the spatial magnitudes occur, he express something which is directly conceivable. 341 The third power of a spatial distance (r^3) represents the measure of a volume in three-dimensional space. The same cannot be said of the temporal magnitudes on the other side of the equation (t^2). 342 For our conception of time forbids us to connect any concrete idea with 'squared time'. 343 We are therefore called upon to find out what form we can give this side of the equation so as to express the time-factor in a manner which is in accord with our conception of time, that is, in linear form. 344 This form readily suggests itself if we consider that we have here to do with a ratio of squares. For such a ratio may be resolved into a ratio of two simple ratios.

345 In this way the equation-- r1^3 / r2^3 = t1^2 / t2^2 assumes the form- r1^3 / r2^3 = (t1 / t2) / (t2 / t1)

346 The right-hand side of the equation is now constituted by the double ratio of the linear values of the periods of two planets, and this is something with which we can connect a quite concrete idea.

347 To see this, let us choose the periods of two definite planets-- say, Earth and Jupiter. 348 For these the equation assumes the following form ('J' and 'E' indicating 'Jupiter' and 'Earth' respectively): rJ^3 / rE^3 = (tJ / tE) / (tE / tJ) Let us now see what meaning we can attach to the two expressions tJ / tE and tE / tJ.

349 During one rotation of Jupiter round the sun the earth circles 12 times round it. This we are wont to express by saying that Jupiter needs 12 earth-years for one rotation; in symbols: tJ / tE = 12 / 1.

350 To find the analogous expression for the reciprocal ratio:

tE / tJ = 1 / 12 we must obviously form the concept 'Jupiter-year', which covers one rotation of Jupiter, just as the concept 'earth-year' covers one rotation of the earth (always round the sun). 351 Measured in this time-scale, the earth needs for one of her rotations 1 / 12 of a Jupiter-year.

352 With the help of these concepts we are now able to express the double ratio of the planetary periods in the following simplified way. 353 If we suppose the measuring of the two planetary periods to be carried out not by the same time-scale, 354 but each by the time-scale of the other, the formula becomes: rJ3 / rE3 = (tJ / tE) / (tE / tJ) = period of Jupiter measured in Earth-years / period of Earth measured in Jupiter-years. 355 Interpreted in this manner, Kepler's third law discloses an intimate interrelatedness of each planet to all the others as co-members of the same cosmic whole. 356 For the equation now tells us that the solar times of the various planets are regulated in such a way that for any two of them the ratio of these times, measured in their mutual time-units, is the same as the ratio of the spaces swept out by their (solar) orbits.

357 Further, by having the various times of its members thus tuned to one another, our cosmic system shows itself to be ordered on a principle which is essentially musical. 358 To see this, we need only recall that the musical value of a given tone is determined by its relation to other tones, whether they sound together in a chord, or in succession as melody. 359 A 'C' alone is musically undefined. It receives its character from its interval-relation to some other tone, say, 'G', together with which it forms a Fifth. 360 As the lower tone of this interval, 'C' bears a definite character; and so does 'G' as the upper tone.

361 Now we know that each interval represents a definite ratio between the periodicities of its two tones. 362 In the case of the Fifth the ratio is 2:3 (in the natural scale). This means that the lower tone receives its character from being related to the upper tone by the ratio 2:3. 363 Similarly, the upper tone receives its character

from the ratio 3:2. 364 The specific character of an interval arising out of the merging of its two tones, therefore, is determined by the ratio of their ratios. 365 In the case of the Fifth this is 4:9. It is this ratio, therefore, which underlies our experience of a Fifth.

366 The cosmic factor corresponding to the periodicity of the single tone in music is the orbital period of the single planet. 367 To the musical interval formed by two tones corresponds the double ratio of the periods of any two planets. 368 Regarded thus, Kepler's law can be expressed as follows: The spatial ordering of our planetary system is determined by the interval-relation in which the different planets stand to each other.

369 By thus unlocking the ideal content hidden in Kepler's third law, we are at the same time enabled to do justice to the way in which he himself announced his discovery. 370 In textbooks and encyclopaedias it is usually said that the discovery of the third law was the surprising result of Kepler's fantastic attempt to prove by external observation what was once taught in the school of Pythagoras, 371 namely, that (in Wordsworth's language): 'By one pervading spirit Of tones and numbers all things are controlled.'

372 Actually, Kepler's great work, Harmonices Mundi, in the last part of which he announces his third law, is entirely devoted to proving the truth of the Pythagorean doctrine that the universe is ordered according to the laws of music. 373 This doctrine sprang from the gift of spiritual hearing still possessed by Pythagoras, by which he could perceive the harmonies of the spheres. 374 It was the aim of his school to keep this faculty alive as long as possible, and with its aid to establish a communicable world-conception. 375 The Pythagorean teaching became the foundation of all later cosmological thinking, right up to the age which was destined to bring to birth the spectator-relationship of human's consciousness with the world. 376 Thus it was left to Copernicus to give humankind the first truly non-Pythagorean picture of the universe.

MATTER

377 When Kepler declared himself in favour of the heliocentric aspect, as indicated by Copernicus, he acknowledged that the universe had grown dumb for human's inner ear. 378 Yet, besides his strong impulse to meet the true needs of his time, there were inner voices telling him of secrets that were hidden behind the veil woven by human's physical perceptions. One of these secrets was the musical order of the world. 379 Such knowledge, however, could not induce him to turn to older world-conceptions in his search for truth. 380 He had no need of them, because there was yet another voice in him which told him that the spiritual order of the world must somehow manifest itself in the body of the world as it lay open to physical perception. 381 Just as a musical instrument, if it is to be a perfect means of bringing forth music, must bear in its build the very laws of music, 382 so must the body of the universe, as the instrument on which the harmonies of the spheres play their spiritual music, bear in its proportions a reflexion of these harmonies. 383 Kepler was sure that investigation of the world's body, provided it was carried out by means of pure observation, must needs lead to a re-establishment of the ancient truth in a form appropriate to the modern mind. 384 Thus Kepler, guided by an ancient spiritual conception of the world, could devote himself to confirming its truth by the most up-to-date methods of research. 385 That his search was not in vain, our examination of the third law has shown.

386 One thing, however, remains surprising-- that Kepler announced his discovery in the form in which it has henceforth engraved itself in the modern mind, while refraining from that analysis of it which we have applied to it here. 387 Yet, in this respect also Kepler proves to have remained true to himself. There is, on the one hand, the form in which Kepler pronounced his discovery; there is, on the other, the context in which he made this pronouncement. 388 We have already pointed out that the third law forms part of Kepler's comprehensive work, Harmonices Mundi.

389 To the modern critic's understanding it appears there like an erratic block. For Kepler this was different. 390 While publishing his discovery in precisely the form in which it is conceived by a mind bent on pure observation, he gave it a setting by which he left no doubt as to his own conception of its ideal content. 391 And as a warning to the future reader not to overlook the message conveyed by this arrangement, he introduced the section of his book which contains the announcement of the law, with the mysterious words about himself: 392 'I have stolen the golden vessels of the Egyptians from which to furnish for my God a holy shrine far from Egypt's confines.'

KNOW THYSELF

Ernst Lehrs

21 Our inquiries have led us to a picture of human as a sensible-super-sensible organism composed of three dynamic aggregates--physical, etheric, astral. 2 As three rungs of a spiritual ladder they point to a fourth, which represents that particular power in human by which you distinguishes yourself from all other beings in Nature. 3 For what makes human differ from all these is that you are not only fitted, as they are, with a once-for-all given mode of spiritual-physical existence peculiar to yourself, 4 but that you are endowed with the possibility of transforming your existence by dint of your free will-- that indeed your humanhood is based on this capacity for self-willed Becoming. 5 To this fourth principle in human we can give no better name than that which every human being can apply to oneself alone and to no other, and which no other can apply to you. This is the name, I. 6 In truth, we describe human in own entirety only if we ascribe to you, in addition to a physical, etheric and astral body, the possession of an I (Ego).

7 Naturally, our previous studies have afforded many opportunities for observing the nature and mode of activity of the I. 8 Still, at the conclusion of these studies it is not redundant to form a concise picture of this part of human's being, with particular regard to

how it works within the three other principles as its sheaths. 9 For in modern psychology, not excluding the branch of it where efforts are made to penetrate into deeper regions of human's being, nothing is less well understood than the true nature of human's egoity.

10 In order to recognise the peculiar function of the I in human, we must first be clear as to how you differs from the other kingdoms of Nature, 11 and how they differ from one another with respect to the mode of action of the physical, etheric and astral forces.

12 The beings of all the kingdoms of Nature are endowed with an aggregate of physical forces in the form of a material body subject to gravity. 13 The same cannot be said of the etheric forces. Only where life is present as an inherent principle-- that is, in plant, animal and human-- 14 is ether at work in the form of an individual etheric organisation, while the mineral is formed by the universal ether from outside. 15 Where life prevails, we are met by the phenomena of birth and death. When a living organism comes to birth, an individual ether-body is formed out of the general etheric substance of the universe. 16 The death of such an organism consists in the separation of the etheric from the physical body and the dissolution of both in their respective mother-realms. 17 So long as an organism is alive, its form is maintained by the ether-body present in it.

18 Our studies have shown that the plant is not devoid of the operation of astral forces. In the plant's life-cycle this comes to clearest expression in its florescence. 19 But it is a working of the astral forces from outside, very much as the ether works on the mineral. 20 As a symptom of this fact we may recall the dependence of the plant on the various outer astronomical rhythms.

21 It is only in animal and human that we find the astral forces working in the form of separate astral bodies. This accounts for their capacity for sensation and volition. 22 Besides the alternation of birth and death, they experience the rhythm of sleeping and waking. 23 Sleep occurs when the astral body leaves the physical and etheric bodies in order to expand

into its planetary mother-sphere, whence it gathers new energy. 24 During this time its action on the physical-etheric aggregate remaining upon earth is similar to that of the astral cosmos upon the plant.

25 Again, in the animal kingdom the ego-principle works as an external force in the form of various group-soul activities which control and regulate the life of the different animal species. 26 It is in the group-ego of the species that we have to look for the source of the wisdom-filled instincts which we meet in the single animals.

27 Only in human does the ego-principle enter as an individual entity into the single physico-etheric-astral organism. 28 Here, however, the succession of stages we have outlined comes to a conclusion. 29 For with the appearance of the I as an individual principle, the preceding evolutionary process-- or, more correctly, the involutionary process-- begins to be reversed. 30 In moving up from one kingdom to the next, we find always one more dynamic principle appearing in a state of separation from its mother-sphere; 31 this continues to the point where the I, through uniting itself with a thus emancipated physico-etheric-astral organism, arrives at the stage of self-consciousness. 32 Once this stage has been reached, however, it falls to the I to reverse the process of isolation, temporarily sanctioned by the cosmos for the sake of human.

33 That it is not in the nature of the I to leave its sheaths in the condition in which it finds them when entering them at the beginning of life, can be seen from the activities it performs in them during the first period after birth. 34 Indeed, in human's early childhood we meet a number of events in which we can perceive something like ur-deeds of the I. 35 They are the acquisition of the faculties of walking, speaking and thinking. What we shall here say about them has, in essentials, already been touched upon in earlier pages. Here, however, we are putting it forward in a new light.

36 Once again we find our attention directed to the threefold structure of human's physical

organism. 37 For the faculty of upright walking is a result of the I's activity in the limb-system of the body; the acquisition of speech takes place in the rhythmic system; and thinking is a faculty based on the nerve-system. 38 Consequently, each of the three achievements comes to pass at a different level of consciousness-sleeping, dreaming, waking. 39 All through the struggle of erecting the body against the pull of gravity, the child is entirely unaware of the activities of own I. 40 In the course of acquiring speech one gains a dim awareness, as though in dream, of own efforts. Some capacity of thinking has to unfold before the first glimmer of true self-consciousness is kindled.

41 Note that the word 'I' is the only one that is not added to the child's vocabulary by way of imitation. Otherwise one would, as some mentally inhibited children do, call all other people 'I' and the self 'you'.

42 This picture of the three ur-deeds of the I can now be amplified in the following way. We know that the region of the bodily limbs is that in which physical, etheric and astral forces interpenetrate most deeply. 43 Consequently, the I can here press forward most powerfully into the physical body and on into the dynamic sphere to which the body is subject. 44 Here the I is active in a way that is 'magic' in the highest degree. Moreover, there is no other action for which the I receives so little stimulus from outside. 45 For, in comparison, the activity that leads to the acquisition of speech is much more of the nature of a reaction to stimuli coming from outside-- the sounds reaching the child from own environment. 46 And it is also with the first words of the language that the first thoughts enter the child's mind. 47 Nothing of the kind happens at the first stage. On the contrary: everything that confronts the I here is of the nature of an obstacle that is to be overcome.

48 There is no learning to speak without the hearing of uttered sounds. As these sounds approach the human being they set the astral body in movement, as we have seen. 49 The movements of the astral body flow towards the larynx, where they are seized by

the I; through they help the I imbues the larynx with the faculty of producing these sounds itself. 50 Here, therefore, the I is active essentially within the astral body which has received its stimulus from outside. 51 In order to understand what impels the I to such action, we must remember the role played by speech in human life: without speech there would be no community among human individuals on earth.

52 An illustration of what the I accomplishes as it enters upon the third stage is provided by the following episode, actually observed. 53 Whilst all the members of a family were sitting at table taking their soup, the youngest member suddenly cried out: 'Daddy spoon ... mummy spoon. ... ' (everyone in turn spoon) ' ... all spoon!' 54 At this moment, from merely designating single objects by names learn't through imitation, the child's consciousness had awakened to connective thinking. 55 That this achievement was a cause of inner satisfaction could be heard in the joyful crescendo with which these ejaculations were made.

56 We know that the presence of waking consciousness within the nerves-and-senses organism rests upon the fact that the connexion between physical body and etheric body is there the most external of all. 57 But precisely because this is so, the etheric body is dominated very strongly by the forces to which the physical head owes its formation. 58 This, too, is not fundamentally new to us. What can now be added is that, in consequence, the physical brain and the part of the etheric body belonging to it-- the etheric brain-- assume a function comparable with that of a mirror, 59 the physical organ representing the reflecting mass and the etheric organ its metallic gloss. 60 When, within the head, the etheric body reflects back the impressions received from the astral body, the I becomes aware of them in the form of mental images (the 'ideas' of the onlooker-philosopher). 61 It is also by way of such reflexion that the I first grows aware of itself-- but as nothing more than an image among images. Here, therefore, it is itself least active.

MATTER

62 If, once again, we compare the three happenings of learning to walk, to speak and to think, we find ourselves faced with the remarkable fact that the progressive lighting up of consciousness from one stage to the next, goes hand in hand with a retrogression in the activity of the I itself. 63 At the first stage, where the I knows least of itself, it is alive in the most direct sense out of its own being; 64 at the second stage, where it is in the dreaming state, it receives the impetus of action through the astral body; 65 at the third stage, where the I wakens to clear self-consciousness, it assumes merely the role of onlooker at the pictures moving within the etheric body.

66 Compare with this the paths to higher faculties of knowledge, Imagination and Inspiration, as we learn't to know them in our previous studies. 67 The comparison shows that exactly the same forces come into play at the beginning of life, when the I endeavours to descend from its pre-earthly, cosmic environment to its earthly existence, 68 as have to be made use of for the ascending of the I from earthly to cosmic consciousness. Only, as is natural, the sequence of steps is reversed.

69 For on the upward way the first deed of the I is that which leads to a wakening in the etheric world: it is a learning to set in motion the etheric forces in the region of the head in such a way that the usual isolation of this part of the etheric body is overcome. 70 Regarded thus, the activity of the I at this stage reveals a striking similarity to the activity applied in the earliest period of childhood at the opposite pole of the organism. 71 To be capable of imaginative sight actually means to be able to move about in etheric space by means of the etheric limbs of the eyes just as one moves about in physical space by means of the physical limbs.

72 Similarly, the acquisition of Inspiration is a resuming on a higher level of the activity exercised by the I with the help of the astral body when learning to speak. And here, too, the functions are reversed.

73 For while the child is stimulated by the spoken sounds one hears to bring own organ of speech into corresponding movements, and so

gradually learns to produce speech, 74 the acquisition of Inspiration, as we have seen, depends on learning to bring the super-sensible forces of the speech-organ into movement in such a way that these forces become the organ for hearing the super-sensible language of the universe.

75 Our knowledge of the threefold structure of human's organism leads us to seek, besides the stages of Imagination and Inspiration, a third stage which is as much germinally present in the body's region of movement, as the two others are in the regions of thought and speech. 76 After what we have learn't in regard to these three, we may assume that the path leading to this third stage consists in producing a condition of wide-awake, 77 tranquil contemplation in the very region where the I is wont to unfold its highest degree of initiative on the lowest level of consciousness.

78 In an elementary manner this attitude of soul was practised by us when, in our earlier studies, we endeavoured to become inner observers of the activity of our own limbs, with the aim of discovering the origin of our concept of mass. 79 It was in this way that a line of observation opened up to us which led to the recognition of the physical substances of the earth as congealed spiritual functions or, we may say, congealed utterances of cosmic will.

80 Cosmic Will, however, does not work into our existence only in such a way that, in the form of old and therefore rigid Will, it puts up resistance against the young will-power of the I, so that in overcoming this resistance the I may waken to self-activity. 81 Cosmic Will is also present in us in an active form. We point here to the penetration by the higher powers of the universe into the forming of the destiny of humanity and of individual human. 82 And here Rudolf Steiner has shown that to a person who succeeds in becoming a completely objective observer of own existence while actively functioning within it 83 as in an elementary way we endeavoured to become observers of our limb actions while engaged in performing them 84 the world

begins to reveal itself as an arena of the activities of divine-spiritual Beings, whose reality and acts he is now able to apprehend through inner awareness. 85 Herewith a third stage of human's faculty of cognition is added to the stages of Imagination and Inspiration. 86 When Rudolf Steiner chose for it the word Intuition he applied this word, also, in its truest meaning. 87 While through Imagination human comes to know of own ether-body as part of own make-up, and correspondingly through Inspiration of own astral body, and thereby recognises the self as participant in the super-sensible forces of the universe, 88 it is through Intuition that you grows into full awareness of your I as a spirit-being among spirit-beings--God-begotten, God-companioned, forever God-ward striving.

The Sixth Book of Divine Panagogue called

ETHICS

THE ETHICS
Benedict de Spinoza

CONCERNING GOD

DEFINITIONS

1 (I.) By that which is 'self-c*aused*' I mean that of which the essence involves existence, or that of which the nature is only conceivable as existent.

2 (II.) A thing is called 'finite *after its kind*' when it can be limited by another thing of the same nature; for instance, a body is called finite because we always conceive another greater body. 3 So, also, a thought is limited by another thought, but a body is not limited by thought, nor a thought by body.

4 (III.) By 'substance' I mean that which is in itself, and is conceived through itself: in other words, that of which a conception can be formed independently of any other conception.

5 (IV.) By 'attribute' I mean that which the intellect perceives *as* constituting the essence of substance.

6 (V.) By 'mode' I mean the modifications *("affectiones") of* substance, or that which exist*s* in, and is conceived through, something other than itself.

7 (VI.) By 'God' I mean a being absolutely infinite-- that is, a substance consisting in infinite attributes, of which each expresses eternal and infinite essentiality.

EXPLANATION

8 I say absolutely infinite, not infinite after its kind: for, of a thing infinite only after its kind, infinite attributes may be denied; 9 but that which is absolutely infinite, contains in its essence whatever expresses reality, and involves no negation.

10 (VII.) That thing is called 'free,' which exists solely by the necessity of its own nature, and of which the action is determined by itself alone. 11 On the other hand, that thing is necessary, or rather constrained, which is determined by something external to itself to a fixed and definite method of existence or action.

12 (VIII.) By 'eternity' I mean existence itself, in so far as it is conceived necessarily to follow

solely from the definition of that which is eternal.

EXPLANATION

13 Existence of this kind is conceived as an eternal truth, like the essence of a thing and, therefore, cannot be explained by means of continuance or time, though continuance may be conceived without a beginning or end.

AXIOMS

14 (I.) Everything which exists, exists either in itself or in something else.

15 (II.) That which cannot be conceived through anything else must be conceived through itself.

16 (III.) From a given definite cause an effect necessarily follows; and, on the other hand, if no definite cause be granted, it is impossible that an effect can follow.

17 (IV.) The knowledge of an effect depends on and involves the knowledge of a cause.

18 (V.) Things which have nothing in common cannot be understood, the one by means of the other; the conception of one does not involve the conception of the other.

19 (VI.) A true idea must correspond with its ideate or object.

20 (VII.) If a thing can be conceived as non-existing, its essence does not involve existence.

PROPOSITIONS

21 (I.) Substance is by nature prior to its modifications.

22 (II.) Two substances, whose attributes are different, have nothing in common.

23 For each must exist in itself, and be conceived through itself; in other words, the conception of one does not imply the conception of the other.

24 (III.) Things which have nothing in common cannot be one the cause of the other.

25 If they have nothing in common, it follows that one cannot be apprehended by means of the other, and, therefore, one cannot be the cause of the other.

26 (IV.) Two or more distinct things are distinguished one from the other, either by the difference of the attributes of the substances, or by the difference of their modifications.

27 Everything which exists, exists either in itself or in something else-- that is, nothing is granted in addition to the understanding, except substance and its modifications. 28 Nothing is, therefore, given besides the understanding, by which several things may be distinguished one from the other, except the substances, or, in other words, their attributes and modifications.

29 (V.) There cannot exist in the universe two or more substances having the same nature or attribute.

30 If several distinct substances be granted, they must be distinguished one from the other, either by the difference of their attributes, or by the difference of their modifications

31 If only by the difference of their attributes, it will be granted that there cannot be more than one with an identical attribute. 32 If by the difference of their modifications-- as substance is naturally prior to its modifications-- it follows that setting the modifications aside, and considering substance in itself, that is truly, 33 there cannot be conceived one substance different from another-- that is, there cannot be granted several substances, but one substance only.

34 (VI.) One substance cannot be produced by another substance.

35 It is impossible that there should be in the universe two substances with an identical attribute, i.e. which have anything common to them both, and, therefore, one cannot be the cause of the other, neither can one be produced by the other.

COROLLARY

36 (VI.) Hence it follows that a substance cannot be produced by anything external to itself. 37 For in the universe nothing is granted, save substances and their modifications. 38 Now substance cannot be produced by another substance, therefore it cannot be produced by anything external to itself. 39 This is shown still more readily by the absurdity of the contradictory. For, if substance be produced by an external cause, the knowledge of it would depend on the knowledge of its cause, and it would itself not be substance.

40 (VII.) Existence belongs to the nature of substances.

41 Substance cannot be produced by anything external, it must, therefore, be its own cause-- that is, its essence necessarily involves existence, or existence belongs to its nature.

42 (VIII.) Every substance is necessarily infinite.

43 There can only be one substance with an identical attribute, and existence follows from its nature; 44 its nature, therefore, involves existence, either as finite or infinite. 45 It does not exist as finite, for it would then be limited by something else of the same kind, which would also necessarily exist; 46 and there would be two substances with an identical attribute, which is absurd. It therefore exists as infinite.

Note-I

47 As finite existence involves a partial negation, and infinite existence is the absolute affirmation of the given nature, it follows that every substance is necessarily infinite.

Note-II

48 No doubt it will be difficult for those who think about things loosely, and have not been accustomed to know them by their primary causes, 49 for such persons make no distinction between the modifications of substances and the substances themselves, and are ignorant of the manner in which things are produced; 50 hence they may attribute to substances the beginning which they observe in natural objects. 51 Those who are ignorant of true causes make complete confusion-- think that trees might talk just as well as humans-- that people might be formed from stones as well as from seed; and imagine that any form might be changed into any other. 52 So, also, those who confuse the two natures, divine and human, readily attribute human passions to the deity, especially so long as they do not know how passions originate in the mind.

53 But, if people would consider the nature of substance, they would have no doubt about the truth of-- *existence*. In fact, this proposition would be a universal axiom, and accounted a truism.

54 For, by substance, would be understood that which is in itself,

and is conceived through itself--that is, something of which the conception requires not the conception of anything else; 55 whereas modifications exist in something external to themselves, and a conception of them is formed by means of a conception of the things in which they exist. 56 Therefore, we may have true ideas of non-existent modifications; for, although they may have no actual existence apart from the conceiving intellect, yet their essence is so involved in something external to themselves that they may through it be conceived. 57 Whereas the only truth substances can have, external to the intellect, must consist in their existence, because they are conceived through themselves.

58 Therefore, for a person to say that one has a clear and distinct--that is, a true-- idea of a substance, but that one is not sure whether such substance exists, 59 would be the same as if you said that you had a true idea, but was not sure whether or no it was false (a little consideration will make this plain); 60 or if anyone affirmed that substance is created, it would be the same as saying that a false idea was true-- in short, the height of absurdity. 61 It must, then, necessarily be admitted that the existence of substance as its essence is an eternal truth. 62 And we can hence conclude by another process of reasoning-- that there is but one such substance. 63 I think that this may profitably be done at once; and, in order to proceed regularly with the demonstration, we must premise:--

64 (1.) The true definition of a thing neither involves nor expresses anything beyond the nature of the thing defined. 65 From this it follows that-- (2.) No definition implies or expresses a certain number of individuals, inasmuch as it expresses nothing beyond the nature of the thing defined. 66 For instance, the definition of a triangle expresses nothing beyond the actual nature of a triangle: it does not imply any fixed number of triangles.

67 (3.) There is necessarily for each individual existent thing a cause why it should exist.

68 (4.) This cause of existence must either be contained in the nature and definition of the thing defined,

or must be postulated apart from such definition.

69 It therefore follows that, if a given number of individual things exist in Nature, there must be some cause for the existence of exactly that number, neither more nor less. 70 For example, if twenty people exist in the universe-- for simplicity's sake, I will suppose them existing simultaneously, and to have had no predecessors--, 71 and we want to account for the existence of these twenty people, it will not be enough to show the cause of human existence in general; 72 we must also show why there are exactly twenty people, neither more nor less: for a cause must be assigned for the existence of each individual. 73 Now this cause cannot be contained in the actual nature of human, for the true definition of human does not involve any consideration of the number twenty.

74 Consequently, the cause for the existence of these twenty people, and, consequently, of each of them, must necessarily be sought externally to each individual. 75 Hence we may lay down the absolute rule, that everything which may consist of several individuals must have an external cause. 76 And, as it has been shown already that existence appertains to the nature of substance, existence must necessarily be included in its definition; and from its definition alone existence must be deducible. 77 But from its definition, we cannot infer the existence of several substances; therefore it follows that there is only one substance of the same nature.

78 (IX.) The more reality or being a thing has, the greater the number of its attributes.

79 (X.) Each particular attribute of the one substance must be conceived through itself.

80 An attribute is that which the intellect perceives of substance, as constituting its essence, and, therefore, must be conceived through itself.

81 It is thus evident that, though two attributes are, in fact, conceived as distinct-- that is, one without the help of the other-- yet we cannot, therefore, conclude that they constitute two entities, or two different substances. 82 For it

is the nature of substance that each of its attributes is conceived through itself, inasmuch as all the attributes it has have always existed simultaneously in it, 83 and none could be produced by any other; but each expresses the reality or being of substance. 84 It is, then, far from an absurdity to ascribe several attributes to one substance: for nothing in Nature is more clear than that each and every entity must be conceived under some attribute, 85 and that its reality or being is in proportion to the number of its attributes expressing necessity or eternity and infinity.

86 Consequently it is abundantly clear, that an absolutely infinite being must necessarily be defined as consisting in infinite attributes, each of which expresses a certain eternal and infinite essence.

87 If anyone now ask, by what sign shall you be able to distinguish different substances, let you read the following propositions, which show that there is but one substance in the universe, 88 and that it is absolutely infinite, wherefore such a sign would be sought in vain.

89 (XI.) God, or substance, consisting of infinite attributes, of which each expresses eternal and infinite essentiality, necessarily exists.

90 If this be denied, conceive, if possible, that God does not exist: then His essence does not involve existence. But this is absurd. Therefore God necessarily exists.

PROOF

91 Of everything whatsoever a cause or reason must be assigned, either for its existence, or for its non-existence-- e.g. 92 if a triangle exist, a reason or cause must be granted for its existence; if, on the contrary, it does not exist, a cause must also be granted, which prevents it from existing, or annuls its existence. 93 This reason or cause must either be contained in the nature of the thing in question, or be external to it. 94 For instance, the reason for the non-existence of a square circle is indicated in its nature, namely, because it would involve a contradiction. 95 On the other hand, the existence of substance follows also solely from its nature, inasmuch as its nature involves existence.

96 But the reason for the existence of a triangle or a circle does not follow from the nature of those figures, but from the order of universal nature in extension. 97 From the latter it must follow, either that a triangle necessarily exists, or that it is impossible that it should exist. 98 So much is self-evident. It follows therefrom that a thing necessarily exists, if no cause or reason be granted which prevents its existence.

99 If, then, no cause or reason can be given, which prevents the existence of God, or which destroys His existence, we must certainly conclude that He necessarily does exist. 100 If such a reason or cause should be given, it must either be drawn from the very nature of God, or be external to Him-- that is, drawn from another substance of another nature. 101 For if it were of the same nature, God, by that very fact, would be admitted to exist. 102 But substance of another nature could have nothing in common with God, and therefore would be unable either to cause or to destroy His existence.

103 As, then, a reason or cause which would annul the divine existence cannot be drawn from anything external to the divine Nature, 104 such cause must perforce, if God does not exist, be drawn from God's own nature, which would involve a contradiction. 105 To make such an affirmation about a being absolutely infinite and supremely perfect is absurd; therefore, neither in the nature of God, nor externally to His nature, can a cause or reason be assigned which would annul His existence. 106 Therefore, God necessarily exists.

PROOF

107 The potentiality of non-existence is a negation of power, and contrariwise the potentiality of existence is a power, as is obvious. 108 If, then, that which necessarily exists is nothing but finite beings, such finite beings are more powerful than a being absolutely infinite, which is obviously absurd; 109 therefore, either nothing exists, or else a being absolutely infinite necessarily exists also. 110 Now we exist either in ourselves, or in something else which necessarily

exists. Therefore a being absolutely infinite-- in other words, God – necessarily exists.

Note

111 In this last proof, I have purposely shown God's existence 'a-posteriori,' so that the proof might be more easily followed, not because, from the same premises, God's existence does not follow 'a priori.' 112 For, as the potentiality of existence is a power, it follows that, in proportion as reality increases in the nature of a thing, so also will it increase its strength for existence. 113 Therefore a being absolutely infinite, such as God, has from Himself an absolutely infinite power of existence, and hence He does absolutely exist. 114 Perhaps there will be many who will be unable to see the force of this proof, inasmuch as they are accustomed only to consider those things which flow from external causes. 115 Of such things, they see that those which quickly come to pass-- that is, quickly come into existence-- quickly also disappear; 116 whereas they regard as more difficult of accomplishment-- that is, not so easily brought into existence-- those things which they conceive as more complicated.

117 However, to do away with this misconception, I need not here show the measure of truth in the proverb, "What comes quickly, goes quickly," 118 nor discuss whether, from the point of view of universal Nature, all things are equally easy, or otherwise: 119 I need only remark that I am not here speaking of things, which come to pass through causes external to themselves, but only of substances which cannot be produced by any external cause. 120 Things which are produced by external causes, whether they consist of many parts or few, owe whatsoever perfection or reality they possess solely to the efficacy of their external cause; 121 wherefore the existence of substance must arise solely from its own nature, which is nothing else but its essence. 122 Thus, the perfection of a thing does not annul its existence, but, on the contrary, asserts it. 123 Imperfection, on the other hand, does annul it; therefore we cannot be more certain of the existence of

anything, than of the existence of a being absolutely infinite or perfect-- that is, of God. 124 For inasmuch as His essence excludes all imperfection, and involves absolute perfection, all cause for doubt concerning His existence is done away, and the utmost certainty on the question is given. 125 This, I think, will be evident to every moderately attentive reader.

126 (XII.) No attribute of substance can be conceived from which it would follow that substance can be divided.

PROOF

127 The parts into which substance as thus conceived would be divided either will retain the nature of substance, or they will not. 128 If the former, then each part will necessarily be infinite, and self-caused, and will perforce consist of a different attribute, so that, in that case, several substances could be formed out of one substance, which is absurd. 129 Moreover, the parts would have nothing in common with their whole, and the whole could both exist and be conceived without its parts, which everyone will admit to be absurd. 130 If we adopt the second alternative-- namely, that the parts will not retain the nature of substance-- then, if the whole substance were divided into equal parts, it would lose the nature of substance, and would cease to exist, which is absurd.

131 (XIII.) Substance absolutely infinite is indivisible.

PROOF

132 If it could be divided, the parts into which it was divided would either retain the nature of absolutely infinite substance, or they would not. 133 If the former, we should have several substances of the same nature, which is absurd. 134 If the latter, then substance absolutely infinite could cease to exist, which is also absurd.

COROLLARY

135 It follows that no substance, and consequently no extended substance, in so far as it is substance, is divisible.

Note

136 The indivisibility of substance may be more easily understood as follows. The nature of substance can only be conceived as infinite, and by a part of substance, nothing else can be understood than finite

substance, which involves a manifest contradiction.

137 (XIV.) Besides God no substance can be granted or conceived.

PROOF

138 As God is a being absolutely infinite, of whom no attribute that expresses the essence of substance can be denied, and He necessarily exists; 139 if any substance besides God were granted, it would have to be explained by some attribute of God, and thus two substances with the same attribute would exist, which is absurd; 140 therefore, besides God no substance can be granted, or consequently be conceived. If it could be conceived, it would necessarily have to be conceived as existent; but this is absurd. 141 Therefore, besides God no substance can be granted or conceived.

COROLLARY-I

142 Clearly, therefore: 1. God is one, that is only one substance can be granted in the universe, and that substance is absolutely infinite, as we have already indicated.

COROLLARY II

143 It follows: 2. That extension and thought are either attributes of God or accidents ("*affectiones*") of the attributes of God.

144 (XV.) Whatsoever is, is in God, and without God nothing can be, or be conceived.

PROOF

145 Besides God, no substance is granted or can be conceived, that is, nothing which is in itself and is conceived through itself. 146 But modes can neither be, nor be conceived without substance; wherefore they can only be in the divine Nature, and can only through it be conceived. 147 But substances and modes form the sum total of existence, therefore, without God nothing can be, or be conceived.

Note

148 Some assert that God, like a human, consists of body and mind, and is susceptible of passions. 149 How far such persons have strayed from the truth is sufficiently evident from what has been said. But these I pass over. 150 For all who have in anywise reflected on the divine Nature deny that God has a body. 151 Of this they find excellent proof in the fact that we understand by body a definite quantity, so long, so broad, so deep, bounded by a certain shape,

and it is the height of absurdity to predicate such a thing of God, a being absolutely infinite. 152 But meanwhile by other reasons with which they try to prove their point, they show that they think corporeal or extended substance wholly apart from the divine Nature, and say it was created by God. 153 Where from the divine Nature can have been created, they are wholly ignorant; thus they clearly show that they do not know the meaning of their own words. 154 I myself have proved sufficiently clearly, at any rate in my own judgment, that no substance can be produced or created by anything other than itself. 155 Further, I showed that besides God no substance can be granted or conceived. Hence we drew the conclusion that extended substance is one of the infinite attributes of God. 156 However, in order to explain more fully, I will refute the arguments of my adversaries, which all start from the following points:--

157 Extended substance, in so far as it is substance, consists, as they think, in parts, wherefore they deny that it can be infinite, or consequently, that it can appertain to God. 158 This they illustrate with many examples, of which I will take one or two. If extended substance, they say, is infinite, let it be conceived to be divided into two parts; each part will then be either finite or infinite. 159 If the former, then infinite substance is composed of two finite parts, which is absurd. If the latter, then one infinite will be twice as large as another infinite, which is also absurd.

160 Further, if an infinite line be measured out in foot lengths, it will consist of an infinite number of such parts; 161 it would equally consist of an infinite number of parts, if each part measured only an inch: therefore, one infinity would be twelve times as great as the other.

162 Lastly, if from a single point there be conceived to be drawn two diverging lines which at first are at a definite distance apart, but are produced to infinity, 163 it is certain that the distance between the two lines will be continually increased, until at length it changes from definite to indefinable. 164 As these

absurdities follow, it is said, from considering quantity as infinite, the conclusion is drawn that extended substance must necessarily be finite, and, consequently, cannot appertain to the nature of God.

165 The second argument is also drawn from God's supreme perfection. God, it is said, inasmuch as He is a supremely perfect being, cannot be passive; but extended substance, insofar as it is divisible, is passive. 166 It follows, therefore, that extended substance does not appertain to the essence of God.

167 Such are the arguments I find on the subject in writers, who by them try to prove that extended substance is unworthy of the divine Nature, and cannot possibly appertain thereto. 168 However, I think an attentive reader will see that I have already answered their propositions; for all their arguments are founded on the hypothesis that extended substance is composed of parts, and such a hypothesis I have shown to be absurd. 169 Moreover, anyone who reflects will see that all these absurdities (if absurdities they be, which I am not now discussing), from which it is sought to extract the conclusion that extended substance is finite, 170 do not at all follow from the notion of an infinite quantity, but merely from the notion that an infinite quantity is measurable, and composed of finite parts: 171 therefore, the only fair conclusion to be drawn is that infinite quantity is not measurable, and cannot be composed of finite parts. 172 This is exactly what we have already proved. Wherefore the weapon which they aimed at us has in reality recoiled upon themselves. 173 If, from this absurdity of theirs, they persist in drawing the conclusion that extended substance must be finite, they will in good sooth be acting like a person who asserts that circles have the properties of squares, 174 and, finding oneself thereby landed in absurdities, proceeds to deny that circles have any center, from which all lines drawn to the circumference are equal. 175 For, taking extended substance, which can only be conceived as infinite, one, and indivisible they assert, in order to prove that it is finite, that it is

composed of finite parts, and that it can be multiplied and divided.

176 So, also, others, after asserting that a line is composed of points, can produce many arguments to prove that a line cannot be infinitely divided. 177 Assuredly it is not less absurd to assert that extended substance is made up of bodies or parts, than it would be to assert that a solid is made up of surfaces, a surface of lines, and a line of points. 178 This must be admitted by all who know clear reason to be infallible, and most of all by those who deny the possibility of a vacuum. 179 For if extended substance could be so divided that its parts were really separate, why should not one part admit of being destroyed, the others remaining joined together as before? 180 And why should all be so fitted into one another as to leave no vacuum? 181 Surely in the case of things, which are really distinct one from the other, one can exist without the other, and can remain in its original condition. 182 As, then, there does not exist a vacuum in Nature (of which anon), but all parts are bound to come together to prevent it, 183 it follows from this that the parts cannot really be distinguished, and that extended substance in so far as it is substance cannot be divided.

184 If anyone asks me the further question, Why are we naturally so prone to divide quantity? I answer, that quantity is conceived by us in two ways; in the abstract and superficially, as we imagine it; or as substance, as we conceive it solely by the intellect.

185 If, then, we regard quantity as it is represented in our imagination, which we often and more easily do, we shall find that it is finite, divisible, and compounded of parts; 186 but if we regard it as it is represented in our intellect, and conceive it as substance, which it is very difficult to do, we shall then, as I have sufficiently proved, find that it is infinite, one, and indivisible. 187 This will be plain enough to all who make a distinction between the intellect and the imagination, especially if it be remembered that matter is everywhere the same, 188 that its parts are not distinguishable, except in so far as we conceive matter as diversely

modified, whence its parts are distinguished, not really, but modally. 189 For instance, water, in so far as it is water, we conceive to be divided, and its parts to be separated one from the other; 190 but not in so far as it is extended substance; from this point of view it is neither separated nor divisible. 191 Further, water, in so far as it is water, is produced and corrupted; but, in so far as it is substance, it is neither produced nor corrupted.

192 I think I have now answered the second argument; it is, in fact, founded on the same assumption as the first-- namely, that matter, in so far as it is substance, is divisible, and composed of parts. 193 Even if it were so, I do not know why it should be considered unworthy of the divine Nature, inasmuch as besides God no substance can be granted, wherefrom it could receive its modifications. 194 All things, I repeat, are in God, and all things which come to pass, come to pass solely through the laws of the infinite nature of God, and follow (as I will shortly show) from the necessity of His essence. 195 Wherefore it can in nowise be said that God is passive in respect to anything other than Himself, 196 or that extended substance is unworthy of the divine Nature, even if it be supposed divisible, so long as it is granted to be infinite and eternal. But enough of this for the present.

197 (XVI.) From the necessity of the divine Nature must follow an infinite number of things in infinite ways-- that is, all things which can fall within the sphere of infinite intellect.

PROOF

198 This proposition will be clear to everyone, who remembers that from the given definition of any thing the intellect infers several properties, which really necessarily follow therefrom (that is, from the actual essence of the thing defined); 199 and it infers more properties in proportion as the definition of the thing expresses more reality, that is, in proportion as the essence of the thing defined involves more reality. 200 Now, as the divine Nature has absolutely infinite attributes, of which each expresses infinite essence after its kind, 201 it

follows that from the necessity of its Nature an infinite number of things (that is, everything which can fall within the sphere of an infinite intellect) must necessarily follow.

COROLLARY-I

202 Hence it follows, that God is the efficient cause of all that can fall within the sphere of an infinite intellect.

COROLLARY-II

203 It also follows that God is a cause in Himself, and not through an accident of His nature.

COROLLARY-III

204 It follows, thirdly, that God is the absolutely first-cause.

205 (XVII.) God acts solely by the laws of His own nature, and is not constrained by anyone.

PROOF

206 We have just shown, that solely from the necessity of the divine Nature, or, what is the same thing, solely from the laws of His nature, an infinite number of things absolutely follow in an infinite number of ways; 207 and we proved, that without God nothing can be nor be conceived; but that all things are in God. 208 Wherefore nothing can exist outside Himself, whereby He can be conditioned or constrained to act. 209 Wherefore God acts solely by the laws of His own nature, and is not constrained by anyone.

COROLLARY-I

210 It follows: 1. That there can be no cause which, either extrinsically or intrinsically, besides the perfection of His own nature, moves God to act.

COROLLARY-II

211 It follows: 2. That God is the sole free cause. For God alone exists by the sole necessity of His nature, and acts by the sole necessity of His own nature, wherefore God is the sole free cause.

Note

212 Others think that God is a free cause, because He can, as they think, bring it about, that those things which we have said follow from His nature-- that is, which are in His power, should not come to pass, or should not be produced by Him. 213 But this is the same as if they said, that God could bring it about, that it should follow from the nature of a triangle that its three interior angles should not be equal to two right angles; or that from a given cause no effect should follow, which is absurd.

214 Moreover, I will show below, without the aid of this proposition, that neither intellect nor will appertain to God's nature. 215 I know that there are many who think that they can show, that supreme intellect and free-will do appertain to God's nature; 216 for they say they know of nothing more perfect, which they can attribute to God, than that which is the highest perfection in ourselves. 217 Further, although they conceive God as actually supremely intelligent, they yet do not believe that He can bring into existence everything which He actually understands, for they think that they would thus destroy God's power. 218 If, they contend, God had created everything which is in His intellect, He would not be able to create anything more, and this, they think, would clash with God's omnipotence; 219 therefore, they prefer to asset that God is indifferent to all things, and that He creates nothing except that which He has decided, by some absolute exercise of will, to create. 220 However, I think I have shown sufficiently clearly that from God's supreme power, or infinite nature, an infinite number of things-- 221 that is, all things have necessarily flowed forth in an infinite number of ways, or always flow from the same necessity; 222 in the same way as from the nature of a triangle it follows from eternity and for eternity, that its three interior angles are equal to two right angles. 223 Wherefore the omnipotence of God has been displayed from all eternity, and will for all eternity remain in the same state of activity. 224 This manner of treating the question attributes to God an omnipotence, in my opinion, far more perfect. 225 For, otherwise, we are compelled to confess that God understands an infinite number of creatable things, which He will never be able to create, 226 for, if He created all that He understands, He would, according to this showing, exhaust His omnipotence, and render Himself imperfect. 227 Wherefore, in order to establish that God is perfect, we should be reduced to establishing at the same time, that He cannot bring to pass everything over which His power extends; 228 this seems to be a hypothesis most

absurd, and most repugnant to God's omnipotence.

229 Further-- to say a word concerning the intellect and the will which we attribute to God--, if intellect and will appertain to the eternal essence of God, we must take these words in some significance quite different from those they usually bear. 230 For intellect and will, which should constitute the essence of God, would perforce be as far apart as the poles from the human intellect and will, in fact, would have nothing in common with them but the name; 231 there would be about as much correspondence between the two as there is between the Dog, the heavenly constellation, and a dog, an animal that barks. 232 This I will prove as follows. If intellect belongs to the divine Nature, it cannot be in Nature, as ours is generally thought to be, posterior to, or simultaneous with the things understood, inasmuch as God is prior to all things by reason of His causality. 233 On the contrary, the truth and formal essence of things is as it is, because it exists by representation as such in the intellect of God. 234 Wherefore the intellect of God, in so far as it is conceived to constitute God's essence, is, in reality, the cause of things, both of their essence and of their existence. 235 This seems to have been recognised by those who have asserted, that God's intellect, God's will, and God's power, are one and the same. 236 As, therefore, God's intellect is the sole cause of things, namely, both of their essence and existence, it must necessarily differ from them in respect to its essence, and in respect to its existence. 237 For a cause differs from a thing it causes, precisely in the quality which the latter gains from the former.

238 For example, a human is the cause of another human's existence, but not of your essence (for the latter is an eternal truth), and, therefore, the two people may be entirely similar in essence, but must be different in existence; 239 and hence if the existence of one of them cease, the existence of the other will not necessarily cease also; 240 but if the essence of one could be destroyed, and be made false, the essence of the other

would be destroyed also. 241 Wherefore, a thing which is the cause both of the essence and of the existence of a given effect, must differ from such effect both in respect to its essence, and also in respect to its existence. 242 Now the intellect of God is the cause both of the essence and the existence of our intellect; 243 therefore, the intellect of God in so far as it is conceived to constitute the divine essence, differs from our intellect both in respect to essence and in respect to existence, nor can it in anywise agree therewith save in name, as we said before. 244 The reasoning would be identical in the case of the will, as anyone can easily see.

245 (XVIII.) God is the indwelling and not the transient cause of all things.

PROOF

246 All things which are, are in God, and must be conceived through God, therefore God is the cause of those things which are in Him.

247 This is our first point. Further, besides God there can be no substance, that is nothing in itself external to God. 248 This is our second point. God, therefore, is the indwelling and not the transient cause of all things.

249 (XIX.) God, and all the attributes of God, are eternal.

PROOF

250 God is substance, which necessarily exists, that is existence appertains to its nature, or (what is the same thing) follows from its definition; therefore, God is eternal. 251 Further, by the attributes of God we must understand that which expresses the essence of the divine substance-- 252 in other words, that which appertains to substance: that, I say, should be involved in the attributes of substance. 253 Now eternity appertains to the nature of substance; therefore, eternity must appertain to each of the attributes, and thus all are eternal.

Note

254 This proposition is also evident from the manner in which I demonstrated the existence of God; it is evident, I repeat, from that proof, that the existence of God, like His essence, is an eternal truth. 255 Further, I have proved the eternity of God, in another

manner, which I need not here repeat.

256 (XX.) The existence of God and His essence are one and the same.

PROOF

257 God and all His attributes are eternal, that is each of His attributes expresses existence. 258 Therefore the same attributes of God which explain His eternal essence, explain at the same time His eternal existence-- in other words, that which constitutes God's essence constitutes at the same time His existence. 259 Wherefore God's existence and God's essence are one and the same.

COROLLARY-I

260 Hence it follows that God's existence, like His essence, is an eternal truth.

COROLLARY-II

261 Secondly, it follows that God, and all the attributes of God, are unchangeable. 262 For if they could be changed in respect to existence, they must also be able to be changed in respect to essence-- that is, obviously, be changed from true to false, which is absurd.

263 (XXI.) All things which follow from the absolute nature of any attribute of God must always exist and be infinite, or, in other words, are eternal and infinite through the said attribute.

PROOF

264 Conceive, if it be possible (supposing the proposition to be denied), that something in some attribute of God can follow from the absolute nature of the said attribute, 265 and that at the same time it is finite, and has a conditioned existence or duration; for instance, the idea of God expressed in the attribute thought. 266 Now thought, in so far as it is supposed to be an attribute of God, is necessarily in its nature infinite. 267 But, in so far as it possesses the idea of God, it is supposed finite. It cannot, however, be conceived as finite, unless it be limited by thought; 268 but it is not limited by thought itself, in so far as it has constituted the idea of God (for so far it is supposed to be finite); 269 therefore, it is limited by thought, in so far as it has not constituted the idea of God, which nevertheless must necessarily exist.

270 We have now granted, therefore, thought not constituting the idea of God, and, accordingly, the idea of God does not naturally follow from its nature in so far as it is absolute thought-- 271 for it is conceived as constituting, and also as not constituting, the idea of God--, which is against our hypothesis. 272 Wherefore, if the idea of God expressed in the attribute thought, or, indeed, anything else in any attribute of God-- for we may take any example, as the proof is of universal application-- 273 follows from the necessity of the absolute nature of the said attribute, the said thing must necessarily be infinite, which was our first point.

274 Furthermore, a thing which thus follows from the necessity of the nature of any attribute cannot have a limited duration. 275 For if it can, suppose a thing, which follows from the necessity of the nature of some attribute, to exist in some attribute of God, 276 for instance, the idea of God expressed in the attribute thought, and let it be supposed at some time not to have existed, or to be about not to exist.

277 Now thought being an attribute of God must necessarily exist unchanged; and beyond the limits of the duration of the idea of God-- 278 supposing the latter at some time not to have existed, or not to be going to exist-- thought would perforce have existed without the idea of God, 279 which is contrary to our hypothesis, for we supposed that, thought being given, the idea of God necessarily flowed therefrom. 280 Therefore the idea of God expressed in thought, or anything which necessarily follows from the absolute nature of some attribute of God, cannot have a limited duration, but through the said attribute is eternal, which is our second point.

281 Bear in mind that the same proposition may be affirmed of anything, which in any attribute necessarily follows from God's absolute nature.

282 (XXII.) Whatsoever follows from any attribute of God, in so far as it is modified by a modification, which exists necessarily and as infinite, through the said attribute, must also exist necessarily and as infinite.

PROOF

283 The proof of this proposition is similar to that of the preceding one.

284 (XXIII.) Every mode, which exists both necessarily and as infinite, must necessarily follow either from the absolute nature of some attribute of God, 285 or from an attribute modified by a modification which exists necessarily, and as infinite.

PROOF

286 A mode exists in something else, through which it must be conceived, that is, it exists solely in God, and solely through God can be conceived. 287 If therefore a mode is conceived as necessarily existing and infinite, it must necessarily be inferred or perceived through some attribute of God, 288 in so far as such attribute is conceived as expressing the infinity and necessity of existence, in other words eternity; that is, in so far as it is considered absolutely. 289 A mode, therefore, which necessarily exists as infinite, must follow from the absolute nature of some attribute of God, 290 either immediately or through the means of some modification, which follows from the absolute nature of the said attribute; that is, which exists necessarily and as infinite.

291 (XXIV.) The essence of things produced by God does not involve existence.

PROOF

292 This proposition is evident. For that of which the nature (considered in itself) involves existence is self-caused, and exists by the sole necessity of its own nature.

COROLLARY

293 Hence it follows that God is not only the cause of things coming into existence, but also of their continuing in existence, that is, in scholastic phraseology, God is cause of the being of things (essendi rerum). 294 For whether things exist, or do not exist, whenever we contemplate their essence, we see that it involves neither existence nor duration; 295 consequently, it cannot be the cause of either the one or the other. God must be the sole cause, inasmuch as to Him alone does existence appertain.

296 (XXV.) God is the efficient cause not only of the existence of things, but also of their essence.

PROOF

297 If this be denied, then God is not the cause of the essence of things; and therefore the essence of things can be conceived without God. This is absurd. Therefore, God is the cause of the essence of things.

Note

298 This proposition follows more clearly. For it is evident thereby that, given the divine Nature, the essence of things must be inferred from it, no less than their existence-- 299 in a word, God must be called the cause of all things, in the same sense as He is called the cause of Himself. This will be made still clearer by the following corollary.

COROLLARY

300 Individual things are nothing but modifications of the attributes of God, or modes by which the attributes of God are expressed in a fixed and definite manner.

301 (XXVI.) A thing which is conditioned to act in a particular manner, has necessarily been thus conditioned by God; and that which has not been conditioned by God cannot condition itself to act.

PROOF

302 That by which things are said to be conditioned to act in a particular manner is necessarily something positive-- this is obvious--; 303 therefore both of its essence and of its existence God by the necessity of His nature is the efficient cause; this is our first point. 304 Our second point is plainly to be inferred therefrom. For if a thing, which has not been conditioned by God, could condition itself, the first part of our proof would be false, and this, as we have shown is absurd.

305 (XXVII.) A thing, which has been conditioned by God to act in a particular way, cannot render itself unconditioned.

306 (XXVIII.) Every individual thing, or everything which is finite and has a conditioned existence, cannot exist or be conditioned to act, unless it be conditioned for existence and action by a cause other than itself, 307 which also is finite, and has a conditioned existence; and likewise this cause cannot in its turn exist, or be conditioned to act, unless it be conditioned for existence and action by another cause, 308 which

also is finite, and has a conditioned existence, and so on to infinity.

PROOF

309 Whatsoever is conditioned to exist and act, has been thus conditioned by God.

310 But that which is finite, and has a conditioned existence, cannot be produced by the absolute nature of any attribute of God; for whatsoever follows from the absolute nature of any attribute of God is infinite and eternal. 311 It must, therefore, follow from some attribute of God, in so far as the said attribute is considered as in some way modified; 312 for substance and modes make up the sum total of existence, while modes are merely modifications of the attributes of God. 313 But from God, or from any of His attributes, in so far as the latter is modified by a modification infinite and eternal, a conditioned thing cannot follow. 314 Wherefore it must follow from, or be conditioned for, existence and action by God or one of His attributes, in so far as the latter are modified by some modification which is finite, and has a conditioned existence. This is our first point. 315 Again, this cause or this modification (for the reason by which we established the first part of this proof) must in its turn be conditioned by another cause, which also is finite, and has a conditioned existence, 316 and, again, this last by another (for the same reason); and so on (for the same reason) to infinity.

Note

317 As certain things must be produced immediately by God, namely those things which necessarily follow from His absolute nature, 318 through the means of these primary attributes, which, nevertheless, can neither exist nor be conceived without God, it follows: (1.) That God is absolutely the proximate cause of those things immediately produced by him. 319 I say absolutely, not after His kind, as is usually stated. For the effects of God cannot either exist or be conceived without a cause. 320 (2.) That God cannot properly be styled the remote cause of individual things, except for the sake of distinguishing these from what He immediately produces, or rather from what follows from His absolute nature. 321 For, by a

remote cause, we understand a cause which is in no way conjoined to the effect. 322 But all things which are, are in God, and so depend on God, that without Him they can neither be nor be conceived.

323 (XXIX.) Nothing in the universe is contingent, but all things are conditioned to exist and operate in a particular manner by the necessity of the divine Nature.

PROOF

324 Whatsoever is, is in God. But God cannot be called a thing contingent. For He exists necessarily, and not contingently. 325 Further, the modes of the divine Nature follow therefrom necessarily, and not contingently; and they thus follow, whether we consider the divine Nature absolutely, or whether we consider it as in any way conditioned to act. 326 Further, God is not only the cause of these modes, in so far as they simply exist, but also in so far as they are considered as conditioned for operating in a particular manner.

327 If they be not conditioned by God, it is impossible, and not contingent, that they should condition themselves; 328 contrariwise, if they be conditioned by God, it is impossible, and not contingent, that they should render themselves unconditioned. 329 Wherefore all things are conditioned by the necessity of the divine Nature, not only to exist, but also to exist and operate in a particular manner, and there is nothing that is contingent.

Note

330 Before going any further, I wish here to explain, what we should understand by Nature viewed as active (Natura naturans), and Nature viewed as passive (Natura naturata). 331 I say to explain, or rather call attention to it, for I think that, from what has been said, it is sufficiently clear, that by Nature viewed as active we should understand that which is in itself, and is conceived through itself, 332 or those attributes of substance, which express eternal and infinite essence, in other words God, in so far as He is considered as a free cause.

333 By Nature viewed as passive I understand all that which follows from the necessity of the nature of

God, or of any of the attributes of God, 334 that is, all the modes of the attributes of God, in so far as they are considered as things which are in God, and which without God cannot exist or be conceived.

335 (XXX.) Intellect, in function (actu) finite, or in function infinite, must comprehend the attributes of God and the modifications of God, and nothing else.

PROOF

336 A true idea must agree with its object; in other words (obviously) that which is contained in the intellect in representation must necessarily be granted in Nature. 337 But in Nature there is no substance save God, nor any modifications save those which are in God, and cannot without God either be or be conceived. 338 Therefore the intellect, in function finite, or in function infinite, must comprehend the attributes of God and the modifications of God, and nothing else.

339 (XXXI.) The intellect in function, whether finite or infinite, as will, desire, love, should be referred to passive Nature and not to active Nature.

PROOF

340 By the intellect we do not (obviously) mean absolute thought, but only a certain mode of thinking, differing from other modes, such as love, desire, and therefore requiring to be conceived through absolute thought. 341 It must, through some attribute of God which expresses the eternal and infinite essence of thought, be so conceived, that without such attribute it could neither be nor be conceived. 342 It must therefore be referred to Nature passive rather than to Nature active, as must also the other modes of thinking.

Note

343 I do not here, by speaking of intellect in function, admit that there is such a thing as intellect in potentiality: 344 but, wishing to avoid all confusion, I desire to speak only of what is most clearly perceived by us, namely, of the very act of understanding, than which nothing is more clearly perceived. 345 For we cannot perceive anything without adding to our knowledge of the act of understanding.

346 (XXXII.) will cannot be called a free cause, but only a necessary cause.

PROOF

347 will is only a particular mode of thinking, like intellect; therefore no volition can exist, nor be conditioned to act, unless it be conditioned by some cause other than itself, which cause is conditioned by a third cause, and so on to infinity. 348 But if will be supposed infinite, it must also be conditioned to exist and act by God, 349 not by virtue of His being substance absolutely infinite, but by virtue of His possessing an attribute which expresses the infinite and eternal essence of thought. 350 Thus, however it be conceived, whether as finite or infinite, it requires a cause by which it should be conditioned to exist and act. 351 Thus it cannot be called a free cause, but only a necessary or constrained cause.

COROLLARY-I

352 Hence it follows, first, that God does not act according to freedom of the will.

COROLLARY-II

353 It follows, secondly, that will and intellect stand in the same relation to the nature of God as do motion, and rest, and absolutely all natural phenomena, which must be conditioned by God to exist and act in a particular manner. 354 For will, like the rest, stands in need of a cause, by which it is conditioned to exist and act in a particular manner.

355 And although, when will or intellect be granted, an infinite number of results may follow, yet God cannot on that account be said to act from freedom of the will, 356 any more than the infinite number of results from motion and rest would justify us in saying that motion and rest act by free-will. 357 Wherefore will no more appertains to God than does anything else in Nature, but stands in the same relation to Him as motion, rest, and the like, 358 which we have shown to follow from the necessity of the divine Nature, and to be conditioned by it to exist and act in a particular manner.

359 (XXXIII.) Things could not have been brought into being by God in any manner or in any order different from that which has in fact obtained.

PROOF

360 All things necessarily follow from the nature of God, and by the nature of God are conditioned to

exist and act in a particular way. 361 If things, therefore, could have been of a different nature, or have been conditioned to act in a different way, so that the order of Nature would have been different, God's nature would also have been able to be different from what it now is; 362 and therefore that different nature also would have perforce existed, and consequently there would have been able to be two or more Gods. This is absurd. 363 Therefore, things could not have been brought into being by God in any other manner.

Note-I

364 As I have thus shown, more clearly than the sun at noonday, that there is nothing to justify us in calling things contingent, 365 I wish to explain briefly what meaning we shall attach to the word contingent; but I will first explain the words necessary and impossible.

366 A thing is called necessary either in respect to its essence or in respect to its cause; for the existence of a thing necessarily follows, either from its essence and definition, or from a given efficient cause. 367 For similar reasons a thing is said to be impossible; namely, inasmuch as its essence or definition involves a contradiction, or because no external cause is granted, which is conditioned to produce such an effect; 368 but a thing can in no respect be called contingent, save in relation to the imperfection of our knowledge.

369 A thing of which we do not know whether the essence does or does not involve a contradiction, or of which, knowing that it does not involve a contradiction, we are still in doubt concerning the existence, because the order of causes escapes us,-- 370 such a thing, I say, cannot appear to us either necessary or impossible. Wherefore we call it contingent or possible.

Note-II

371 It clearly follows from what we have said, that things have been brought into being by God in the highest perfection, inasmuch as they have necessarily followed from a most perfect nature. 372 Nor does this prove any imperfection in God, for it has compelled us to affirm His

perfection. 373 From its contrary proposition, we should clearly gather-- as I have just shown--, that God is not supremely perfect, 374 for if things had been brought into being in any other way, we should have to assign to God a nature different from that, which we are bound to attribute to Him from the consideration of an absolutely perfect being.

375 I do not doubt, that many will scout this idea as absurd, and will refuse to give their minds up to contemplating it, 376 simply because they are accustomed to assign to God a freedom very different from that which we have deduced. They assign to Him, in short, absolute free-will. 377 However, I am also convinced that if such persons reflect on the matter, and duly weigh in their minds our series of propositions, they will reject such freedom as they now attribute to God, 378 not only as nugatory, but also as a great impediment to organised knowledge. 379 There is no need for me to repeat what I have said. But, for the sake of my opponents, I will show further, that although it be granted that will pertains to the essence of God, 380 it nevertheless follows from His perfection, that things could not have been by Him created other than they are, or in a different order; 381 this is easily proved, if we reflect on what our opponents themselves concede, namely, that it depends solely on the decree and will of God, that each thing is what it is. If it were otherwise, God would not be the cause of all things.

382 Further, that all the decrees of God have been ratified from all eternity by God Himself. If it were otherwise, God would be convicted of imperfection or change. 383 But in eternity there is no such thing as when, before, or after; hence it follows solely from the perfection of God, that God never can decree, or never would have decreed anything but what is; 384 that God did not exist before His decrees, and would not exist without them. 385 But, it is said, supposing that God had made a different universe, or had ordained other decrees from all eternity concerning Nature and Her order, we could not therefore conclude any imperfection in God. 386 But persons who say this must admit

that God can change His decrees. For if God had ordained any decrees concerning Nature and Her order, different from those which He has ordained-- 387 in other words, if He had willed and conceived something different concerning Nature-- He would perforce have had a different intellect from that which He has, and also a different will. 388 But if it were allowable to assign to God a different intellect and a different will, without any change in His essence or His perfection, 389 what would there be to prevent Him changing the decrees which He has made concerning created things, and nevertheless remaining perfect? 390 For His intellect and will concerning things created and their order are the same, in respect to His essence and perfection, however they be conceived.

391 Further, all the philosophers whom I have read admit that God's intellect is entirely actual, and not at all potential; as they also admit that God's intellect, and God's will, and God's essence are identical, 392 it follows that, if God had had a different actual intellect and a different will, his essence would also have been different; 393 and thus, as I concluded at first, if things had been brought into being by God in a different way from that which has obtained, God's intellect and will, that is (as is admitted) His essence would perforce have been different, which is absurd.

394 As these things could not have been brought into being by God in any but the actual way and order which has obtained; and as the truth of this proposition follows from the supreme perfection of God; 395 we can have no sound reason for persuading ourselves to believe that God did not wish to create all the things which were in His intellect, and to create them in the same perfection as He had understood them.

396 But, it will be said, there is in things no perfection nor imperfection; that which is in them, and which causes them to be called perfect or imperfect, good or bad, depends solely on the will of God. 397 If God had so willed, he might have brought it about that what is now perfection should be extreme imperfection, and vice versa. 398 What is such an

assertion, but an open declaration that God, who necessarily understands that which He wishes, might bring it about by His will, that He should understand things differently from the way in which He does understand them? 399 This-- as we have just shown-- is the height of absurdity. Wherefore, I may turn the argument against its employers, as follows:-- All things depend on the power of God.

400 In order that things should be different from what they are, God's will would necessarily have to be different. 401 But God's will cannot be different-- as we have just most clearly demonstrated-- from God's perfection. Therefore neither can things be different. 402 I confess, that the theory which subjects all things to the will of an indifferent deity, and asserts that they are all dependent on His fiat, is less far from the truth than the theory of those, who maintain that God acts in all things with a view of promoting what is good. 403 For these latter persons seem to set up something beyond God, which does not depend on God, but which God in acting looks to as an exemplar, or which He aims at as a definite goal. 404 This is only another name for subjecting God to the dominion of destiny, an utter absurdity in respect to God, whom we have shown to be the first and only free cause of the essence of all things and also of their existence. 405 I need, therefore, spend no time in refuting such wild theories.

406 (XXXIV.) God's power is identical with His essence.

PROOF

407 From the sole necessity of the essence of God it follows that God is the cause of Himself and of all things. 408 Wherefore the power of God, by which He and all things are and act, is identical with His essence.

408 (XXXV.) Whatsoever we conceive to be in the power of God, necessarily exists.

PROOF

409 Whatsoever is in God's power, must be comprehended in His essence in such a manner, that it necessarily follows therefrom, and therefore necessarily exists.

410 (XXXVI.) There is no cause from whose nature some effect does not follow.

PROOF

411 Whatsoever exists expresses God's nature or essence in a given conditioned manner; 412 that is, whatsoever exists, expresses in a given conditioned manner God's power, which is the cause of all things, therefore an effect must necessarily follow.

IN CONCLUSION

413 In the foregoing I have explained the nature and properties of God. I have shown that He necessarily exists, that He is one: 414 that He is, and acts solely by the necessity of His own nature; that He is the free cause of all things, and how He is so; that all things are in God, and so depend on Him, that without Him they could neither exist nor be conceived; 415 lastly, that all things are predetermined by God, not through His free-will or absolute fiat, but from the very nature of God or infinite power. 416 I have further, where occasion afforded, taken care to remove the prejudices, which might impede the comprehension of my demonstrations. 417 Yet there still remain misconceptions not a few, which might and may prove very grave hindrances to the understanding of the concatenation of things, as I have explained it above. 418 I have therefore thought it worthwhile to bring these misconceptions before the bar of reason.

419 All such opinions spring from the notion commonly entertained, that all things in nature act as humans themselves act, namely, with an end in view. 420 It is accepted as certain, that God Himself directs all things to a definite goal-- for it is said that God made all things for human, and human that you might worship Him. 421 I will, therefore, consider this opinion, asking first, why it obtains general credence, and why all humans are naturally so prone to adopt it?; 422 secondly, I will point out its falsity; and, lastly, I will show how it has given rise to prejudices about good and bad, right and wrong, praise and blame, order and confusion, beauty and ugliness, and the like. 423 However, this is not the place to deduce these misconceptions from the nature of the human mind: it will be sufficient here, if I assume as a starting point, what ought to be universally admitted, 424

namely, that all humans are born ignorant of the causes of things, that all have the desire to seek for what is useful to them, and that they are conscious of such desire. 425 Herefrom it follows, first, that humans think themselves free inasmuch as they are conscious of their volitions and desires, and never even dream, in their ignorance, of the causes which have disposed them so to wish and desire. 426 Secondly, that humans do all things for an end, namely, for that which is useful to them, and which they seek. 427 Thus it comes to pass that they only look for a knowledge of the final causes of events, and when these are learned, they are content, as having no cause for further doubt. 428 If they cannot learn such causes from external sources, they are compelled to turn to considering themselves, 429 and reflecting what end would have induced them personally to bring about the given event, and thus they necessarily judge other natures by their own. 430 Further, as they find in themselves and outside themselves many means which assist them not a little in the search for what is useful, 431 for instance, eyes for seeing, teeth for chewing, herbs and animals for yielding food, the sun for giving light, the sea for breeding fish, etc, they come to look on the whole of Nature as a means for obtaining such conveniences. 432 Now as they are aware, that they found these conveniences and did not make them, they think they have cause for believing, that some other being has made them for their use. 433 As they look upon things as means, they cannot believe them to be self-created; 434 but, judging from the means which they are accustomed to prepare for themselves, they are bound to believe in some ruler or rulers of the universe endowed with human freedom, who have arranged and adapted everything for human use. 435 They are bound to estimate the nature of such rulers-- having no information on the subject-- in accordance with their own nature, 436 and therefore they assert that the gods ordained everything for the use of human, in order to bind human to themselves and obtain from Him the highest honour.

437 Hence also it follows, that everyone thought out for the self, according to own abilities, a different way of worshipping God, 438 so that God might love you more than your fellows, and direct the whole course of Nature for the satisfaction of your blind cupidity and insatiable avarice. 439 Thus the prejudice developed into superstition, and took deep root in the human mind; and for this reason everyone strove most zealously to understand and explain the final causes of things; 440 but in their endeavour to show that Nature does nothing in vain, i.e. nothing which is useless to human, they only seem to have demonstrated that Nature, the gods, and humans are all mad together. 441 Consider, I pray you, the result: among the many helps of Nature they were bound to find some hindrances, such as storms, earthquakes, diseases, etc: 442 so they declared that such things happen, because the gods are angry at some wrong done to them by humans, or at some fault committed in their worship. 443 Experience day by day protested and showed by infinite examples, that good and evil fortunes fall to the lot of pious and impious alike; 444 still they would not abandon their inveterate prejudice, for it was more easy for them to class such contradictions among other unknown things of whose use they were ignorant, 445 and thus to retain their actual and innate condition of ignorance, than to destroy the whole fabric of their reasoning and start afresh. 446 They therefore laid down as an axiom, that God's judgments far transcend human understanding. 447 Such a doctrine might well have sufficed to conceal the truth from the human race for all eternity, if mathematics had not furnished another standard of verity in considering solely the essence and properties of figures without regard to their final causes. 448 There are other reasons-- which I need not mention here-- besides mathematics, which might have caused humans' minds to be directed to these general prejudices, and have led them to the knowledge of the truth.

449 I have now sufficiently explained my first point. There is

no need to show at length, that Nature has no particular goal in view, and that final causes are mere human figments. 450 This, I think, is already evident enough, both from the causes and foundations on which I have shown such prejudice to be based, 451 and, in fact, all those propositions in which I have shown, that everything in Nature proceeds from a sort of necessity, and with the utmost perfection. 452 However, I will add a few remarks in order to overthrow this doctrine of a final cause utterly. That which is really a cause it considers as an effect, and vice versa: 453 it makes that which is by nature first to be last, and that which is highest and most perfect to be most imperfect.

454 Passing over the questions of cause and priority as self-evident, it is plain that the effect is most perfect which is produced immediately by God; 455 the effect which requires for its production several intermediate causes is, in that respect, more imperfect. 456 But if those things which were made immediately by God were made to enable Him to attain His end, then the things which come after, for the sake of which the first were made, are necessarily the most excellent of all.

457 Further, this doctrine does away with the perfection of God: for, if God acts for an object, He necessarily desires something which He lacks. 458 Certainly, theologians and metaphysicians draw a distinction between the object of want and the object of assimilation; still they confess that God made all things for the sake of Himself, not for the sake of creation. 459 They are unable to point to anything prior to creation, except God Himself, as an object for which God should act, 460 and are therefore driven to admit-- as they clearly must--, that God lacked those things for whose attainment He created means, and further that He desired them.

461 We must not omit to notice that the followers of this doctrine, anxious to display their talent in assigning final causes, have imported a new method of argument in proof of their theory-- 462 namely, a reduction, not to the impossible, but to ignorance; thus showing that they have no other

method of exhibiting their doctrine. 463 For example, if a stone falls from a roof onto someone's head, and kills him, they will demonstrate by their new method, that the stone fell in order to kill the human; 464 for, if it had not by God's will fallen with that object, how could so many circumstances-- and there are often many concurrent circumstances-- have all happened together by chance?

465 Perhaps you will answer that the event is due to the facts that the wind was blowing, and the human was walking that way. 466 "But why," they will insist, "was the wind blowing, and why was the human at that very time walking that way?" 467 If you again answer that the wind had then sprung up because the sea had begun to be agitated the day before, the weather being previously calm, and that the human had been invited by a friend, 468 they will again insist: "But why was the sea agitated, and why was the human invited at that time?" So they will pursue their questions from cause to cause, till at last you take refuge in the will of God-- in other words, the sanctuary of ignorance. 469 So, again, when they survey the frame of the human body, they are amazed; and being ignorant of the causes of so great a work of art, 470 conclude that it has been fashioned, not mechanically, but by divine and supernatural skill, and has been so put together that one part shall not hurt another.

471 Hence anyone who seeks for the true causes of miracles, and strives to understand natural phenomena as an intelligent being, and not to gaze at them like a fool, 472 is set down and denounced as an impious heretic by those, whom the masses adore as the interpreters of Nature and the gods. 473 Such persons know that, with the removal of ignorance, the wonder which forms their only available means for proving and preserving their authority would vanish also. 474 But I now quit this subject, and pass on to my third point.

475 After humans persuaded themselves, that everything which is created is created for their sake, they were bound to consider as the chief quality in everything that

which is most useful to themselves, 476 and to account those things the best of all which have the most beneficial effect on humankind. 477 Further, they were bound to form abstract notions for the explanation of the nature of things, such as goodness, badness, order, confusion, warmth, cold, beauty, deformity, and so on; 478 and from the belief that they are free agents arose the further notions of praise and blame, sin and merit.

479 I will speak of these latter hereafter, when I treat of human nature; the former I will briefly explain here.

480 Everything which conduces to health and the worship of God they have called good, everything which hinders these objects they have styled bad; 481 and inasmuch as those who do not understand the nature of things do not verify phenomena in any way, but merely imagine them after a fashion, and mistake their imagination for understanding, 482 such persons firmly believe that there is an order in things, being really ignorant both of things and their own nature. 483 When phenomena are of such a kind, that the impression they make on our senses requires little effort of imagination, and can consequently be easily remembered, we say that they are well-ordered; 484 if the contrary, that they are ill-ordered or confused.

485 Further, as things which are easily imagined are more pleasing to us, humans prefer order to confusion-- as though there were any order in Nature, except in relation to our imagination-- and say that God has created all things in order; 486 thus, without knowing it, attributing imagination to God, unless, indeed, they would have it that God foresaw human imagination, and arranged everything, so that it should be most easily imagined. 487 If this be their theory, they would not, perhaps, be daunted by the fact that we find an infinite number of phenomena, far surpassing our imagination, and very many others which confound its weakness. But enough has been said on this subject. 488 The other abstract notions are nothing but modes of imagining, in which the imagination is differently

affected: 489 though they are considered by the ignorant as the chief attributes of things, inasmuch as they believe that everything was created for the sake of themselves; 490 and, according as they are affected by it, style it good or bad, healthy or rotten or corrupt. 491 For instance, if the motion which objects we see communicate to our nerves be conducive to health, the objects causing it are styled beautiful; if a contrary motion be excited, they are styled ugly.

492 Things which are perceived through our sense of smell are styled fragrant or fetid; if through our taste, sweet or bitter, full-flavoured or insipid; if through our touch, hard or soft, rough or smooth, etc.

493 Whatsoever affects our ears is said to give rise to noise, sound, or harmony. In this last case, there are people lunatic enough to believe, that even God Himself takes pleasure in harmony; 494 and philosophers are not lacking who have persuaded themselves, that the motion of the heavenly bodies gives rise to harmony-- 495 all of which instances sufficiently show that everyone judges of things according to the state of own brain, or rather mistakes for things the forms of own imagination. 496 We need no longer wonder that there have arisen all the controversies we have witnessed, and finally scepticism: for, although human bodies in many respects agree, yet in very many others they differ; 497 so that what seems good to one seems confused to another; what is pleasing to one displeases another, and so on. 498 I need not further enumerate, because this is not the place to treat the subject at length, and also because the fact is sufficiently well known.

499 It is commonly said: "So many people, so many minds; everyone is wise in own way; brains differ as completely as palates."

500 All of which proverbs show, that humans judge of things according to their mental disposition, and rather imagine than understand: 501 for, if they understood phenomena, they would, as mathematicians attest, be convinced, if not attracted, by what I have urged.

ETHICS

502 We have now perceived, that all the explanations commonly given of Nature are mere modes of imagining, and do not indicate the true nature of anything, but only the constitution of the imagination; 503 and, although they have names, as though they were entities, existing externally to the imagination, I call them entities imaginary rather than real; 504 and, therefore, all arguments against us drawn from such abstractions are easily rebutted.

505 Many argue in this way. If all things follow from a necessity of the absolutely perfect nature of God, why are there so many imperfections in Nature? 506 such, for instance, as things corrupt to the point of putridity, loathsome deformity, confusion, evil, sin, etc. 507 But these reasoners are, as I have said, easily confuted, for the perfection of things is to be reckoned only from their own nature and power; 508 things are not more or less perfect, according as they are serviceable or repugnant to humankind. 509 To those who ask why God did not so create all humans, that they should be governed only by reason, I give no answer but this: because matter was not lacking to humans for the creation of every degree of perfection from highest to lowest; 510 or, more strictly, because the laws of human nature are so vast, as to suffice for the production of everything conceivable by an infinite intelligence.

511 Such are the misconceptions I have undertaken to note; if there are any more of the same sort, everyone may easily dissipate them for the self with the aid of a little reflection.

`

ETHICS AND AESTHETICS
George Stuart Fullerton

COMMON SENSE ETHICS

2 We may, if we choose, study the actions of people merely with a view to ascertaining what they are and describing them accurately. 2 Something like this is done by the anthropologist, who gives us an account of the manners and customs of the various races of humankind; 3 he tells us ‘what is’; he may not regard it as within his

province at all to inform us regarding ‘what ought to be’.

4 But humans do not merely act; they judge their actions in the light of some norm or standard, and they distinguish between them as right and wrong. 5 The systematic study of actions as right and wrong yields us the science of ethics.

6 Like psychology, ethics is a special science. It is concerned with a somewhat limited field of investigation, and is not to be confounded with other sciences. It has a definite aim distinct from theirs. 7 And, also like psychology, ethics is classed as one of the philosophical sciences, and its relation to philosophy is supposed to be closer than that of such sciences as physics and mathematics. 8 It is fair to ask why this is so. Why cannot ethics proceed on the basis of certain assumptions independently, and leave to some other discipline the whole question of an inquiry into the nature and validity of those assumptions?

9 About half a century ago Dr. william Whewell, one of the most learned of English scholars, wrote a work entitled "*The Elements of Morality*," 10 in which he attempted to treat the science of ethics as it is generally admitted that one may treat the science of geometry. 11 The book was rather widely read a generation since, but we meet with few references to it in our time.

12 "Morality and the philosophy of morality," argues the author, "differ in the same manner and in the same degree as geometry and the philosophy of geometry. 13 Of these two subjects, geometry consists of a series of positive and definite propositions, deduced one from another, in succession, by rigourous reasoning, and all resting upon certain definitions and self-evident axioms. 14 The philosophy of geometry is quite a different subject; it includes such inquiries as these: Whence is the cogency of geometrical proof? 15 What is the evidence of the axioms and definitions? What are the faculties by which we become aware of their truth? and the like. 16 The two kinds of speculation have been pursued, for the most part, by two different classes of persons,-- the geometers and the metaphysicians; 17 for it has been

far more the occupation of metaphysicians than of geometers to discuss such questions as I have stated, the nature of geometrical proofs, geometrical axioms, the geometrical faculty, and the like. 18 And if we construct a complete system of geometry, it will be almost exactly the same, whatever be the views which we take on these metaphysical questions."

19 Such a system Dr. Whewell wishes to construct in the field of ethics. His aim is to give us a view of morality in which moral propositions are "deduced from axioms, by successive steps of reasoning, so far as to form a connected system of moral truth." 20 Such a "sure and connected knowledge of the duties of human" would, he thinks, be of the greatest importance.

21 In accordance with this purpose, Dr. Whewell assumes that humanity, justice, truth, purity, order, earnestness, and moral purpose are fundamental principles of human action; 22 and he thinks that all who admit as much as this will be able to go on with him in his development of a system of moral rules to govern the life of human.

23 It would hardly be worthwhile for me to speak at length of a way of treating ethics so little likely to be urged upon the attention of the reader who busies the self with the books which are appearing in our own day, 24 were it not that we have here an admirable illustration of the attempt to teach ethics as though it were such a science as geometry. 25 The shortcomings of the method become very evident to one who reads the work attentively.

26 Thus, we are forced to ask ourselves, have we really a collection of ultimate moral principles which are analogous to the axioms of geometry? 27 For example, to take but a single instance, Dr. Whewell formulates the Principle of Truth as follows: "We must conform to the universal understanding among people which the use of language implies"; 28 and he remarks later; "The rules: Lie not, Perform your promise, are of universal validity; and the conceptions of lie and of promise are so simple and distinct

that, in general, the rules may be directly and easily applied."

29 Now, we are struck by the fact that this affirmation of the universal validity of the principle of truth is made in a chapter on "*Cases of Conscience*," in a chapter concerned with what seem to be conflicts between duties; 30 and this chapter is followed by one which treats of "*Cases of Necessity*," i.e. cases in which a person is to be regarded as justified in violating common rules when there seems to be urgent reason for so doing. 31 We are told that the moralist cannot say: Lie not, except in great emergencies; but must say: Lie not at all. 32 But we are also told that he must grant that there are cases of necessity in which transgressions of moral rules are excusable; and this looks very much as if he said: Go on and do the thing while I close my eyes.

33 This hardly seems to give us a "sure and connected knowledge of the duties of human" deduced from axiomatic principles. 34 On what authority shall we suspend for the time being this axiomatic principle or that? 35 Is there some deeper principle which lends to each of them its authority, and which may, for cause, withdraw it? 36 There is no hint of such in the treatment of ethics which we are considering, and we seem to have on our hands, not so much a science, as a collection of practical rules, of the scope of which we are more or less in the dark.

37 The interesting thing to notice is that this view of ethics is very closely akin to that adapted unconsciously by the majority of the persons we meet who have not interested themselves much in ethics as a science.

38 By the time that we have reached years of discretion we are all in possession of a considerable number of moral maxims. 39 We consider it wrong to steal, to lie, to injure our neighbour. Such maxims lie in our minds side by side, and we do not commonly think of criticising them.

40 But now and then we face a situation in which one maxim seems to urge one course of action and another maxim a contrary one. 41 Shall we tell the truth and the whole truth, when so doing will

bring grave misfortune upon an innocent person? 42 And now and then we are brought to the realisation that all people do not admit the validity of all our maxims. 43 Judgments differ as to what is right and what is wrong. Who shall be the arbiter? 44 Not infrequently a rough decision is arrived at in the assumption that we have only to interrogate "conscience", 45 in the assumption, in other words, that we carry a watch which can be counted upon to give the correct time, even if the timepieces of our neighbours are not to be depended upon.

46 The common sense ethics cannot be regarded as very systematic and consistent, or as very profound. 47 It is a collection of working rules, of practical maxims; and, although it is impossible to overestimate its value as a guide to life, its deficiencies, when it is looked at critically, become evident, I think, even to thoughtful persons who are not scientific at all.

48 Many writers on ethics have simply tried to turn this collection of working rules into a science, somewhat as Dr. Whewell has done. 49 This is the peculiar weakness of those who have been called the "intuitionalists"-- 50 though I must warn the reader against assuming that this term has but the one meaning, and that all those to whom it has been applied should be placed in the same class. 51 Here it is used to indicate those who maintain that we are directly aware of the validity of certain moral principles, must accept them as ultimate, and need only concern ourselves with the problem of their application.

ETHICS AND PHILOSOPHY

52 When John Locke maintained that there are no "innate practical principles," or innate moral maxims, he pointed in evidence to the "enormities practiced without remorse" in different ages and by different peoples. The list he draws up is a curious and an interesting one.

53 In our day it has pretty generally come to be recognised by thoughtful people that a person's judgments as to right and wrong reflect the phase of civilisation, or the lack of it, which one

represents, 54 and that their significance cannot be understood when we consider them apart from their historic setting. 55 This means that no human's conscience is set up as an ultimate standard, but that every human's conscience is regarded as furnishing material which the science of ethics must take into account.

56 May we, broadening the basis upon which we are to build, and studying the manners, customs, and moral judgments of all sorts and conditions of people, develop an empirical science of ethics which will be independent of philosophy?

57 It does not seem that we can do this. We are concerned with psychological phenomena, and their nature and significance are by no means beyond dispute. 58 For example, there is the feeling of moral obligation, of which ethics has so much to say. What is this feeling, and what is its authority? Is it a thing to be explained? Can it impel a person, let us say, a bigot, to do wrong? 59 And what can we mean by credit and discredit, by responsibility and free choice, and other concepts of the sort? 60 All this must remain very vague to one who has not submitted own ethical concepts to reflective analysis of the sort that we have a right to call philosophical.

61 Furthermore, it does not seem possible to decide what a person should or should not do, without taking into consideration the circumstances in which you are placed. 62 The same act may be regarded as benevolent or the reverse according to its context. 63 If we will but grant the validity of the premises from which the medieval churchman reasoned, 64 we may well ask whether, in laying hands violently upon those who dared to form independent judgments in matters of religion, one was not conscientiously doing own best for own fellow-people. 65 He tried by all means to save some, and to what he regarded as a most dangerous malady he applied a drastic remedy. By what standard shall we judge him?

66 There can be no doubt that our doctrine of the whole duty of human must be conditioned by our view of the nature of the world in which human lives and of human's

place in the world. 67 Has ethics nothing to do with religion? If we do not believe in God, and if we think that human's life ends with the death of the body, it is quite possible that we shall set for you an ethical standard which we should have to modify if we adopted other beliefs. 68 The relation of ethics to religion is a problem that the student of ethics can scarcely set aside. 69 It seems, then, that the study of ethics necessarily carries us back to world problems which cannot be approached except by the path of philosophical reflection. 70 We shall see in Chapter-24 that the theistic problem certainly belongs to this class.

71 It is worthy of our consideration that the vast majority of writers on ethics have felt strongly that their science runs out into metaphysics. We can scarcely afford to treat their testimony lightly. 72 Certainly it is not possible for one who has no knowledge of philosophy to understand the significance of the ethical systems which have appeared in the past. 73 The history of ethics may be looked upon as a part of the history of philosophy. Only on the basis of some general view as to Nature and human have people decided what human ought to do. 74 As we have seen above, this appears sufficiently reasonable.

AESTHETICS

75 Of aesthetics, or the science of the beautiful, I shall say little. There is somewhat the same reason for including it among the philosophical sciences that there is for including ethics.

76 Those who have paid little attention to science or to philosophy are apt to dogmatise about what is and what is not beautiful just as they dogmatise about what is and what is not right. 77 They say unhesitatingly; This object is beautiful, and that one is ugly. It is as if they said: This one is round, and that one square.

78 Often it quite escapes their attention that what they now regard as beautiful struck them as unattractive a short time before; 79 and will, perhaps, when the ceaseless change of the fashions has driven it out of vogue, seem strange and unattractive once

more. 80 Nor do they reflect upon the fact that others, who seem to have as good a right to an opinion as they, do not agree with them in their judgments; 81 nor upon the further fact that the standard of beauty is a thing that has varied from age to age, differs widely in different countries, and presents minor variations in different classes even in the same community.

82 The dogmatic utterances of those who are keenly susceptible to the aesthetic aspects of things but are not given to reflection 83 stand in striking contrast to the epitome of the popular wisdom expressed in the skeptical adage that there is no disputing about tastes.

84 We cannot interpret this adage broadly and take it literally, for then we should have to admit that humans' judgments as to the beautiful cannot constitute the material of a science at all, and that there can be no such thing as progress in the fine arts. 85 The notion of progress implies a standard, and an approximation to an ideal. 86 Few would dare to deny that there has been progress in such arts as painting and music; and when one has admitted so much as this, one has virtually admitted that a science of aesthetics is, at least, possible.

87 The science studies the facts of the aesthetic life as ethics studies the facts of the moral life. It can take no human's taste as furnishing a standard: it must take every human's taste as a fact of significance.

88 It is driven to reflective analysis-- to such questions as, what is beauty? and what is meant by aesthetic progress? 89 It deals with elusive psychological facts the significance of which is not easily grasped.

90 It is a philosophical science, and is by no means in a position to follow a beaten path, dispensing with a reflective analysis of its materials.

ETHICS

ÆSTHETICS DEALS WITH THE MOST GENERAL CONDITIONS OF BEAUTY. SUBJECTIVISTIC AND FORMALISTIC TENDENCIES

Ralph Barton Perry

3 Æsthetics is the formulation, as independently as possible of special subject-matter, of that which conditions beauty. 2 As logic commonly refers to a judgment of truth, so æsthetics at any rate refers to a judgment implied in appreciation. 3 But while it is generally admitted that truth itself is by no means limited to the form of the judgment, the contrary is frequently maintained with reference to beauty. 4 The aphorism, *De gustibus non est disputandum*, expresses a common opinion to the effect that beauty is not a property belonging to the object of which it is predicated, but a property generated by the appreciative consciousness. 5 According to this opinion there can be no beauty except in the case of an object's presence in an individual experience. 6 Investigators must of necessity refuse to leave individual caprice in complete possession of the field, but they have in many cases occupied themselves entirely with the ‘state of æsthetic enjoyment’ in the hope of discovering its constant factors. 7 The opposing tendency defines certain formal characters which the beautiful object must possess. 8 Evidently the latter school will attribute a more profound philosophical importance to the conception of beauty, since for them it is a principle that obtains in the world of being. 9 This was the first notable contention, that of Plato. But even with the emphasis laid upon the subjective aspect of the æsthetic experience, great metaphysical importance may be attached to it, 10 where, as in the case of the German Romanticists, reality is deliberately construed as a spiritual life which is to be appreciated rather than understood.

11 As in the case of logic, a strong impulse has manifested itself in æsthetics to deal with groups of objects that lie within its province, rather than directly with its concepts and principles. 12 The first special treatise on æsthetics, the "Poetics" of Aristotle, belongs

to this type of inquiry, as does all criticism of art in so far as it aims at the formulation of general principles.

13 Ethics, the oldest and most popular of the normative sciences, is the formulation, as independently as possible of special subject-matter, of that which conditions goodness of conduct. 14 Ethics is commonly concerned with goodness only in so far as it is predicated of conduct, or of character, which is a more or less permanent disposition to conduct. 15 Since conduct, in so far as good, is said to constitute moral goodness, ethics may be defined as the formulation of the general principles of morality. 16 The principles so formulated would be those virtually employed to justify conduct, or to disprove the imputation of immorality.

17 The student of this science is confronted with a very considerable diversity of method and differentiation of problems. 18 The earliest and most profound opposition of doctrine in ethics arose from the differences of interpretation of which the teaching of Socrates is capable. 19 His doctrine is, as we have seen, verbally expressed in the proposition, virtue is knowledge. Socrates was primarily concerned to show that there is no real living without an understanding of the significance of life. 20 To live well is to know the end of life, the good of it all, and to govern action with reference to that end. 21 Virtue is therefore the practical wisdom that enables you to live consistently with your real intention. But what is the real intention, the end or good of life? 22 In the "Protagoras," where Plato represents Socrates as expounding his position, virtue is interpreted to mean prudence, or foresight of pleasurable and painful consequences. 23 You who knows, possesses all virtue in that you are qualified to adapt yourself to the real situation and to gain the end of pleasure. 24 All humans, indeed, seek pleasure, but only virtuous humans seek it wisely and well.

25 "And do you, Protagoras, like the rest of the world, call some pleasant things evil and some painful things good?-- 26 for I am rather disposed to say that things are good in as far as they are

pleasant, if they have no consequences of another sort, and in as far as they are painful they are bad."

27 According to this view painful things are good only when they lead eventually to pleasure, and pleasant things evil only when their painful consequences outweigh their pleasantness. 28 Hence moral differences reduce to differences of skill in the universal quest for pleasure, and ‘sensible gratification is the ultimate standard of moral value’. 29 This ancient doctrine, known as hedonism, expressing as it does a part of life that will not suffer itself for long to be denied, is one of the great perennial tendencies of ethical thought. 30 In the course of many centuries it has passed through a number of phases, varying its conception of pleasure from the tranquility of the wise person to the sensuous titillation of the sybarite, and from the individualism of the latter to the universalism of the humanitarian. 31 But in every case it shows a respect for the natural human, praising morality for its disciplinary and instrumental value in the service of such human wants as are the outgrowth of the animal instinct of self-preservation.

RATIONALISM

32 But if a human's life be regarded as a truer representation of own ideals than is own spoken theory, there is little to identify Socrates with the hedonists. 33 At the conclusion of the defence of his own life, which Plato puts into his mouth in the well-known "Apology," he speaks thus:

34 "When my sons are grown up, I would ask you, O my friends, to punish them; and I would have you trouble them, as I have troubled you, if they seem to care about riches, or anything, more than about virtue; 35 or if they pretend to be something when they are really nothing,-- then reprove them, as I have reproved you, for not caring about that for which they ought to care, and thinking that they are something when they are really nothing."

36 It is plain that the man Socrates cared little for the pleasurable or painful consequences of his acts,

provided they were worthy of the high calling of human nature. A human's virtue would now seem to possess an intrinsic nobility. 37 If knowledge be virtue, then on this basis it must be because knowledge is itself excellent. Virtue as knowledge contributes to the good by constituting it. 38 We meet here with the rationalistic strain in ethics. It praises conduct for the inherent worth which it may possess if it express that ‘reason’ which the Stoics called "the ruling part." 39 The riches of wisdom consist for the hedonist in their purchase of pleasure. For the rationalist, on the other hand, wisdom is not coin, but itself the very substance of value.

40 Rationalism has undergone modifications even more significant than those of hedonism, and involving at least one radically new group of conceptions. 41 Among the Greeks rationalism and hedonism alike are eudæmonistic. They aim to portray the fullness of life that makes "the happy human." 42 In the ethics of Aristotle, whose synthetic mind weaves together these different strands, the Greek ideal finds its most complete expression as "the high-minded human," with all own powers and trappings. 43 But the great spiritual transformation which accompanied the decline of Greek culture and the rise of Christianity, brought with it a new moral sensibility, which finds in human no virtue of the self, but only through the grace of God.

44 "And the virtues themselves," says St. Augustine, "if they bear no relation to God, are in truth vices rather than virtues; 45 for although they are regarded by many as truly moral when they are desired as ends in themselves and not for the sake of something else, they are, nevertheless, inflated and arrogant, and therefore not to be viewed as virtues but as vices."

46 The new ideal is that of renunciation, obedience, and resignation. Ethically this expresses itself in ‘pietism’. 47 Virtue is good neither in itself nor on account of its consequences, but because it is conformable to the will of God. 48 The extreme inwardness of this ideal is characteristic of an age that despaired of attainment, whether of pleasure or knowledge. 49 To

all, even the persecuted, it is permitted to obey, and so gain entrance into the kingdom of the children of God. 50 But as every special study tends to rely upon its own conceptions, pietism, involving as it does a relation to God, is replaced by rigourism and intuitionism. 51 The former doctrine defines virtue in terms of the inner attitude which it expresses. It must be done in the spirit of dutifullness, because one ought, and through sheer respect for the law which one's moral nature affirms. 52 Intuitionism has attempted to deal with the source of the moral law by defining conscience as a special faculty or sense, qualified to pass directly upon moral questions, and deserving of implicit obediences. 53 It is characteristic of this whole tendency to look for the spring of virtuous living, not in a good which such living obtains, but in a law to which it owes obedience.

54 This third general ethical tendency has thus been of the greatest importance in emphasising the consciousness of duty, and has brought both hedonism and rationalism to a recognition of its fundamental importance. 55 Ethics must deal not only with the moral ideal, but also with the ground of its appeal to the individual, and your obligation to pursue it. 56 In connection with this recognition of moral responsibility, the problem of human freedom has come to be regarded in the light of an inevitable point of contact between ethics and metaphysics. 57 That which is absolutely binding upon the human will can be determined only in view of some theory of its ultimate nature. 58 On this account the rationalistic and hedonistic motives are no longer abstractly sundered, as in the days of the Stoics and Epicureans, but tend to be absorbed in broader philosophical tendencies. 59 Hedonism appears as the sequel to naturalism; or, more rarely, as part of a theistic system whose morality is divine legislation enforced by an appeal to motives of pleasure and pain. 60 Rationalism, on the other hand, tends to be absorbed in rationalistic or idealistic philosophies, where human's rational nature is construed as

own bond of kinship with the universe.

61 Ethics has exhibited from the beginning a tendency to universalise its conceptions and take the central place in metaphysics. 62 Thus with Plato good conduct was but a special case of goodness, the good being the most general principle of reality. 63 In modern times Fichte and his school have founded an ethical metaphysics upon the conception of duty. 64 In these cases ethics can be distinguished from metaphysics only by adding to the study of the good or of duty, a study of the special physical, psychological, and social conditions under which goodness and dutifullness may obtain in human life. 65 It is possible to attach the name of ethics, and we have seen the same to be true of logic, either to a realm of ideal truth or to that realm wherein the ideal is realised in humanity.

THE VIRTUES, CUSTOMS, AND INSTITUTIONS

66 A systematic study of ethics requires that the virtues, or types of moral practice, shall be interpreted in the light of the central conception of good, or of conscience. 67 Justice, temperance, wisdom, and courage were praised by the Greeks. Christianity added self-sacrifice, humility, purity, and benevolence. 68 These and other virtues have been defined, justified, and co-ordinated with the aid of a standard of moral value or a canon of duty.

69 There is in modern ethics a pronounced tendency, parallel to those already noted in logic and æsthetics, to study such phenomena belonging to its field as have become historically established. 70 A very considerable investigation of custom, institutions, and other social forces has led to a contact of ethics with anthropology and sociology scarcely less significant than that with metaphysics.

ETHICS

ABSOLUTE REALISM
Ralph Barton Perry

THE PHILOSOPHER'S TASK, AND THE PHILOSOPHER'S OBJECT, OR THE ABSOLUTE

4 No one has understood better than the philosophers that they cannot hope to be popular with people of practical common-sense. 2 Indeed, it has commonly been a matter of pride with them. The classic representation of the philosopher's faith in the self is to be found in Plato's "Republic." 3 The philosopher is there portrayed in the famous cave simile as one who having seen the light itself can no longer distinguish the shadows which are apparent to those who sit perpetually in the twilight.

4 Within the cave of shadows they are indeed less at their ease than those who have never seen the sun. 5 But since they knows the source of the shadows, their knowledge surrounds that of the shadow connoisseurs. 6 And their equanimity need not suffer from the contempt of those whom they understands better than they understand themselves. 7 The history of philosophy is due to the dogged persistence with which the philosophers has taken themselves seriously and endured the poor opinion of the world.

8 But the pride of the philosopher has done more than perpetuate the philosophical outlook and problem; it has led to the formulation of a definite philosophical conception, and of two great philosophical doctrines. 9 The conception is that of the absolute; and the doctrines are that of the absolute being, and that of the absolute self or mind. The former of these doctrines is the topic of the present chapter.

10 Among the early Greeks the rôle of the philosopher was one of superlative dignity. In point of knowledge they was less easily satisfied than other people. 11 They thought beyond immediate practical problems, devoting the self to a profounder reflection, that could not but induce in one a sense of superior intellectual worth. 12 The familiar was not binding upon them, for their thought was emancipated from routine and superficiality.

13 Furthermore their intellectual courage and resolution did not permit them to indulge in triviality, doubt, or paradox. They sought their own with a faith that could not be denied. 14 Even Heraclitus the Dark, who was also called "the Weeping Philosopher," because he found at the very heart of Nature that transiency which the philosophical mind seeks to escape, felt himself to be exalted as well as isolated by that insight. 15 But this sentiment of personal aloofness led at once to a division of experience. One who knows truly belongs to another and more abiding world. 16 As there is a philosophical way of thought, there is a philosophical way of life, and a philosophical object. 17 Since the philosopher and the common person do not see alike, the terms of their experience are incommensurable. In Parmenides the Eleatic this motive is most strikingly exhibited. 18 There is a ‘Way of Truth’ which diverges from the ‘Way of Opinion’. The philosopher walks the former way alone. 19 And there is an object of truth, accessible only to one who takes this way of truth. Parmenides finds this object to be the content of pure affirmation.

20 "One path only is left for us to speak of, namely, that ‘It is’. In it are very many tokens that what is, is uncreated and indestructible, alone, complete, immovable, and without end. Nor was it ever, nor will it be; for now it is, all at once, a continuous one."

21 The philosophy of Parmenides, commonly called the Eleatic Philosophy, is notable for this emergence of the pure concept of absolute being as the final object of knowledge. 22 The philosopher aims to discover that which is, and so turns away from that which is not or that which ceases to be. 23 The negative and transient aspects of experience only hinder them in their search for the eternal. 24 It was the great Eleatic insight to realise that the outcome of thought is thus predetermined; that the answer to philosophy is contained in the question of philosophy. 25 The philosopher, in that they resolutely avoids all partiality, relativity, and superficiality, must affirm a complete, universal, and ultimate being as the very object of that perfect knowledge which

they means to possess. 26 This object is known in the history of these philosophies as the ‘infinite’ or ‘absolute’.

27 The Eleatic reasons somewhat as follows. The philosopher seeks to know ‘what is’. 28 The object of their knowledge will then contain as its primary and essential predicate, that of being. It is a step further to define being in terms of this essential predicate.

29 Parmenides thinks of being as a power or strength, a positive self-maintenance to which all affirmations refer. 30 The remainder of the Eleatic philosophy is the analysis of this concept and the proof of its implications. Being must persist through all change, and span all chasms. 31 Before being there can be only nothing, which is the same as to say that so far as being is concerned there is no before. 32 Similarly there can be no after or beyond. There can be no motion, change, or division of being, because being will be in all parts of every division, and in all stages of every process. 33 Hence being is "uncreated and indestructible, alone, complete, immovable, and without end."

34 The argument turns upon the application to ‘being’ as a whole of the meaning and the implications of only being. Being is the affirmative or positive. From that alone, one can derive only such properties as eternity or unity. 35 For generation and decay and plurality may belong to that which is also affirmative and positive, but not to that which is affirmative and positive only. 36 The Eleatic philosophy is due, then, to the determination to derive the whole of reality from the bare necessity of being, to cut down reality to what flows entirely from the assertion of its only known necessary aspect, that of being. 37 We meet here in its simplest form a persistent rationalistic motive, the attempt to derive the universe from the isolation and analysis of its most universal character. 38 As in the case of every well-defined philosophy, this motive is always attended by a "besetting" problem. Here it is the accounting for what, empirically at least, is alien to that universal character. 39 And this difficulty is emphasised rather

than resolved by Parmenides in his designation of a limbo of opinion, "in which is no true belief at all," to which the manifold of common experience with all its irrelevancies can be relegated.

40 The Eleatic philosophy, enriched and supplemented, appears many centuries later in the rigourous rationalism of Spinoza. With Spinoza philosophy is a demonstration of necessities after the manner of geometry. 41 Reality is to be set forth in theorems derived from fundamental axioms and definitions. 42 As in the case of Parmenides, these necessities are the implications of the very problem of being. The philosopher's problem is made to solve itself. 43 But for Spinoza that problem is more definite and more pregnant. The problematic being must not only be, but must be sufficient to itself. 44 What the philosopher seeks to know is primarily an intrinsic entity. Its nature must be independent of other natures, and my knowledge of it independent of my knowledge of anything else. 45 Reality is something which need not be sought further. So construed, being is in Spinoza's philosophy termed substance. 46 It will be seen that to define substance is to affirm the existence of it, for substance is so defined as to embody the very qualification for existence. 47 Whatever exists exists under the form of substance, as that "which is in itself, and is conceived through itself: in other words, that of which a conception can be formed independently of any other conception."

48 There remains but one further fundamental thesis for the establishment of the Spinozistic philosophy, the thesis which maintains the exclusive existence of the one "absolutely infinite being," or God. 49 The exclusive existence of God follows from His existence, because of the exhaustiveness of His nature. 50 His is the nature "consisting in infinite attributes, of which each expresses eternal and infinite essentiality." 51 He will contain all meaning, and all possible meaning, within His fixed and necessary constitution. 52 It is evident that if such a God exist, nothing can fall outside of Him. One such substance must be the

only substance. But upon what grounds are we to assert God's existence?

53 To proceed further with Spinoza's philosophy we must introduce two terms which are scarcely less fundamental in his system than that of substance. 54 The one of these is "attribute," by which he means ‘kind’ or general property; the other is "mode," by which he means ‘case’ or individual thing. 55 Spinoza's proof of God consists in showing that no single mode, single attribute, or finite group of modes or attributes, can be a substance; but only an infinite system of all modes of all attributes. 56 Translated into common speech this means that neither kinds nor cases, nor special groups of either, can stand alone and be of themselves, but only the unity of all possible cases of all possible kinds.

57 The argument concerning the possible substantiality of the case or individual thing is relatively simple. Suppose an attribute or kind, ‘A’, of which there are cases ‘am’{1}, ‘am’{2}, ‘am’{3}, etc. 58 The number of cases is never involved in the nature of the kind, as is seen for example in the fact that the definition of triangle prescribes no special number of individual triangles. 59 Hence ‘am’{1}, ‘am’{2}, ‘am’{3}, etc., must be explained by something outside of their nature. Their being cases of ‘A’ does not account for their existing severally. 60 This is Spinoza's statement of the argument that individual events, such as motions or sensations, are not self-dependent, but belong to a context of like events which are mutually dependent.

61 The question of the attribute is more difficult. Why may not an attribute as a complete domain of interdependent events, itself be independent or substantial? 62 Spinoza's predecessor, Descartes, had maintained precisely that thesis in behalf of the domain of thought and the domain of space. 63 Spinoza's answer rests upon the famous ontological argument, inherited from scholasticism and generally accepted in the first period of modern philosophy. The evidence of existence, he declares, is clear and distinct conceivability.

64 "For a person to say that he has a clear and distinct-- that is, a true-- idea of a substance, but that he is not sure whether such substance exists, would be the same as if he said that he had a true idea, but was not sure whether or no it was false."

65 Now we can form a clear and distinct idea of an absolutely infinite being that shall have all possible attributes. 66 This idea is a well-recognised standard and object of reference for thought. But it is a conception which is highly qualified, not only through its clearness and distinctness, but also through its abundance of content. 67 It affirms itself therefore with a certainty that surpasses any other certainty, because it is supported by each and every other certainty, and even by the residuum of possibility. 68 If any intelligible meaning be permitted to affirm itself, so much the more irresistible is the claim of this infinitely rich meaning. 69 Since every attribute contributes to its validity, the being with infinite attributes is infinitely or absolutely valid. 70 The conclusion of the argument is now obvious. If the being constituted by the infinite attributes exists, it swallows up all possibilities and exists exclusively. 71 The vulnerable point in Spinoza's argument can thus be expressed: that which is important is questionable, and that which is unquestionable is of doubtful importance. 72 Have I indeed a clear and distinct idea of an absolutely infinite being? The answer turns upon the meaning of the phrase "idea of." 73 It is true I can add to such meaning as I apprehend the thought of possible other meaning, and suppose the whole to have a definiteness and systematic unity like that of the triangle. 74 But such an idea is problematic. I am compelled to use the term "possible," and so to confess the failure of definite content to measure up to my idea. 75 My idea of an absolutely infinite being is like my idea of a universal language: I can think of it, but I cannot think it out, for lack of data or because of the conflicting testimony of other data. 76 If I mean the infinity of my being to be a term of inclusiveness, and to insist that the all must be, and that there can be

nothing not included in the all, I can scarcely be denied. But it is reasonable to doubt the importance of such a truth. 77 If, on the other hand, I mean that my infinite being shall have the compactness and organic unity of a triangle, I must admit that such a being is indeed problematic. 78 The degree to which the meaning of the part is dependent upon the meaning of the whole, or the degree to which the geometrical analogy is to be preferred to the analogy of aggregates, like the events within a year, is a problem that falls quite outside Spinoza's fundamental arguments.

79 But the advance of Spinoza over the Eleatics must not be lost sight of. The modern philosopher has so conceived being as to provide for parts within an individual unity. 80 The geometrical analogy is a most illuminating one, for it enables us to understand how manyness may be indispensable to a being that is essentially unitary. 81 The triangle as triangle is one. But it could not be such without sides and angles. The unity is equally necessary to the parts, for sides and angles of a triangle could not be such without an arrangement governed by the nature triangle. 82 The whole of nature may be similarly conceived: as the reciprocal necessity of 'Natura naturans', or Nature defined in respect of its unity, and 'Natura naturata', or Nature specified in detail.

83 There is some promise here of a reconciliation of the 'Way of Opinion' with the 'Way of Truth'. Opinion would be a gathering of detail, truth a comprehension of the intelligible unity. 84 Both would be provided for through the consideration that whatever is complete and necessary must be made up of incompletenesses that are necessary to it.

85 This consideration, however, does not receive its most effective formulation in Spinoza. The isolation of the parts, the actual severalty and irrelevance of the modes, still presents a grave problem. 86 Is there a kind of whole to which not only parts but fragments, or parts in their very incompleteness, are indispensable? 87 This would seem to be true of a 'progression' or 'development', since that would require both perfection as its end, and degrees

of imperfection as its stages. 88 Spinoza was prevented from making much of this idea by his rejection of the principle of ‘teleology’. 89 He regarded appreciation or valuation as a projection of personal bias. "Nature has no particular goal in view," and "final causes are mere human figments." 90 "The perfection of things is to be reckoned only from their own nature and power." 91 The philosophical method which Spinoza here repudiates, the interpretation of the world in moral terms, is ‘Platonism’, 92 an independent and profoundly important movement, belonging to the same general realistic type with Eleaticism and Spinozism. 93 Absolute being is again the fundamental conception. Here, however, it is conceived that being is primarily not affirmation or self-sufficiency, but the ‘good’ or ‘ideal’. 94 There are few great metaphysical systems that have not been deeply influenced by Platonism; hence the importance of understanding it in its purity. 95 To this end we must return again to the early Greek conception of the philosopher; for Platonism, like Eleaticism, is a sequel to the philosopher's self-consciousness.

96 Although the first Greek philosophers, such men as Thales, Heraclitus, Parmenides, and Empedocles, were clearly aware of their distinction and high calling, it by no means follows that they were good judges of themselves. 97 Their sense of intellectual power was unsuspecting; and they praised philosophy without definitely raising the question of its meaning. 98 They were like unskilled players who try all the stops and scales of an organ, and know that somehow they can make a music that exceeds the noises, monotones or simple melodies of those who play upon lesser instruments. 99 They knew their power rather than their instrument or their art. The first philosophers, in short, were self-conscious but not self-critical.

100 The immediately succeeding phase in the history of Greek philosophy was a curtailment, but only in the most superficial sense a criticism, of the activity of the philosopher. 101 In the Periclean Age philosophy suffered more

from inattention than from refutation. The scepticism of the sophists, who were the knowing people of this age, was not so much conviction as indisposition. 102 They failed to recognise the old philosophical problem; it did not appeal to them as a genuine problem. 103 The sophists were the intellectual people of an age of ‘humanism’, ‘individualism’, and ‘secularism’. 104 These were years in which the circle of human society, the state with its institutions, citizenship with its manifold activities and interests, bounded the horizon of thought. 105 What need to look beyond? Life was not a problem, but an abundant opportunity and a sense of capacity. 106 The world was not a mystery, but a place of entertainment and a sphere of action. 107 Of this the sophists were faithful witnesses. In their love of novelty, irreverence, impressionism, elegance of speech, and above all in their praise of individual efficiency, they preached and pandered to their age. 108 Their public, though it loved to abuse them, was the greatest sophist of them all--brilliant and capricious, incomparably rich in all but wisdom. 109 The majority belonged to what Plato called "the sight-loving, art-loving, busy class." 110 This is an age, then, when the human of practical common-sense is preëminent, and the philosopher with own dark sayings has passed away. 111 The pride of wisdom has given way to the pride of power and the pride of cleverness. 112 The many people pursue the many goods of life, and there is no spirit among them all who, sitting apart in contemplation, wonders at the meaning of the whole.

113 But in their midst there moved a strange prophet, whom they mistook for one of themselves. 114 Socrates was not one who prayed in the wilderness, but a man of the streets and the market-place, who talked rather more incessantly than the rest, and apparently with less right. 115 He did not testify to the truth, but pleaded ignorance in extenuation of an exasperating habit of asking questions. 116 There was, however, a humour and a method in his innocence that arrested attention. He was a

formidable adversary in discussion from his very irresponsibility; 117 and he was especially successful with the more rhetorical sophists because he chose his own weapons, and substituted critical analysis, question and answer, for the long speeches to which these teachers were habituated by their profession. 118 He appeared to be governed by an insatiable inquisitiveness, and a somewhat malicious desire to discredit those who spoke with authority.

119 But to those who knew him better, and especially to Plato, who knew him best, Socrates was at once the sweetest and most compelling spirit of his age. 120 There was a kind of truth in the quality of his character. He was perhaps the first of all reverent men. 121 In the presence of conceit his self-depreciation was ironical, but in another presence it was most genuine, and his deepest spring of thought and action. 122 This other presence was his own ideal. Socrates was sincerely humble because, expecting so much of philosophy, he saw his own deficiency. 123 Unlike the unskilled player, he did not seek to make music; but he loved music, and knew that such music as is indeed music was beyond his power. 124 On the other hand he was well aware of his superiority to those in whom self-satisfaction was possible because they had no conception of the ideal. 125 Of such he could say in truth that they did not know enough even to realise the extent of their ignorance. 126 The world has long been familiar with the vivid portrayal of the Socratic consciousness which is contained in Plato's "Apology." 127 Socrates had set out in life with the opinion that his was an age of exceptional enlightenment. 128 But as he came to know people he found that after all no one of them really knew what he was about. Each "sight-loving, art-loving, busy" man was quite blind to the meaning of life. 129 While he was capable of practical achievement, his judgments concerning the real virtue of his achievements were conventional and ungrounded, a mere reflection of tradition and opinion.

130 When asked concerning the meaning of life, or the ground of

his opinions, he was thrown into confusion or aggravated to meaningless reiteration. 131 Such people, Socrates reflected, were both unwise and confirmed in their folly through being unconscious of it. 132 Because he knew that vanity is vanity, that opinion is indeed mere opinion, Socrates felt himself to be the wisest man in a generation of dogged unwisdom.

133 It is scarcely necessary to point out that this insight, however negatively it be used, is a revelation of positive knowledge. 134 Heraclitus and Parmenides claimed to know; Socrates disclaimed knowledge for reasons. Like all real criticism this is at once a confounding of error and a prophecy of truth. 135 The truth so discovered is indeed not ordinary truth concerning historical or physical things, but not on that account less significant and necessary. 136 This truth, it will also be admitted, is virtually rather than actually set forth by Socrates himself. 137 He knew that life has some meaning which those who live with conviction desire at heart to realise, and that knowledge has principles with which those who speak with conviction intend to be consistent. 138 There is, in short, a rational life and a rational discourse. 139 Furthermore, a rational life will be a life wisely directed to the end of the good; and a rational discourse one constructed with reference to the real natures of things, and the necessities which flow from these natures. 140 But Socrates did not conclusively define either the meaning of life or the form of perfect knowledge. 141 He testified to the necessity of some such truths, and his testimony demonstrated both the blindness of his contemporaries and also his own deficiency.

142 The character and method of Socrates have their best foil in the sophists, but their bearing on the earlier philosophers is for our purposes even more instructive. 143 Unlike Socrates these philosophers had not made a study of the task of the philosopher. They were philosophers--" spectators of all time and all existence"; 144 but they were precritical or dogmatic philosophers, to whom it had not occurred to define the

requirements of philosophy. 145 They knew no perfect knowledge other than their own actual knowledge. They defined being and interpreted life without reflecting upon the quality of the knowledge whose object is being, or the quality of insight that would indeed be practical wisdom. 146 But when through Socrates the whole philosophical prospect is again revealed after the period of humanistic concentration, it is as an ideal whose possibilities, whose necessities, are conceived before they are realised. 147 Socrates celebrates the rôle of the philosopher without assigning it to himself. The new philosophical object is the philosopher himself; and the new insight a knowledge of knowledge itself. 148 These three types of intellectual procedure, dogmatic speculation concerning being, humanistic interest in life, and the self-criticism of thought, form the historical preparation for Plato, 149 the philosopher who defined being as the ideal of thought, and upon this ground interpreted life.

150 There is no more striking case in history of the subtle continuity of thought than the relation between Plato and his master Socrates. 151 The wonder of it is due to the absence of any formulation of doctrine on the part of Socrates himself. He only lived and talked; and yet Plato created a system of philosophy in which he is faithfully embodied. 152 The form of embodiment is the dialogue, in which the talking of Socrates is perpetuated and conducted to profounder issues, and in which his life is both rendered and interpreted. 153 But as the vehicle of Plato's thought preserves and makes perfect the Socratic method, so the thought itself begins with the Socratic motive and remains to the end an expression of it. 154 The presentiment of perfect knowledge which distinguished Socrates from his contemporaries becomes in Plato the clear vision of a realm of ideal truth.

155 Plato begins his philosophy with the philosopher and the philosopher's interest. 156 The philosopher is a lover, who like all lovers longs for the beautiful. But he is the supreme lover, for he loves not the individual beautiful

object but the Absolute Beauty itself. 157 He is a lover too in that he does not possess, but somehow apprehends his object from afar. Though imperfect, he seeks perfection; though standing like all his fellows in the twilight of half-reality, he faces toward the sun. 158 Now it is the fundamental proposition of the Platonic philosophy that reality is the sun itself, or the perfection whose possession every wise thinker covets, whose presence would satisfy every longing of experience. 159 The real is that beloved object which is "truly beautiful, delicate, perfect, and blessed." There is both a serious ground for such an affirmation and an important truth in its meaning. 160 The ground is the evident incompleteness of every special judgment concerning experience. We understand only in part, and we know that we understand only in part. 161 What we discover is real enough for practical purposes, but even common-sense questions the true reality of its objects. 162 Special judgments seem to terminate our thought abruptly and arbitrarily. We give "the best answer we can," but such answers do not come as the completion of our thinking. 163 Our thought is in some sense surely a seeking, and it would appear that we are not permitted to rest and be satisfied at any stage of it. 164 If we do so we are like the sophists-- blind to our own ignorance. But it is equally true that our thought is straightforward and progressive. 165 We are not permitted to return to earlier stages, but must push on to that which is not less, but more, than what we have as yet found. 166 There is good hope, then, of understanding what the ideal may be from our knowledge of the direction which it impels us to follow.

167 But to understand Plato's conception of the progression of experience we must again catch up the Socratic strain which he weaves into every theme. 168 For Socrates, student of life and humankind, all objects were objects of interest, and all interests practical interests. 169 One is ignorant when one does not know the good of things; opinionative when one rates things by conventional standards; wise when

one knows their real good. 170 In Platonism this practical interpretation of experience appears in the principle that the object of perfect knowledge is ‘the good’. 171 The nature of things which one seeks to know better is the good of things, the absolute being which is the goal of all thinking is the very good itself. 172 Plato does not use the term good in any merely utilitarian sense. Indeed it is very significant that for Plato there is no cleavage between theoretical and practical interests. 173 To be morally good is to know the good, to set one's heart on the true object of affection; and to be theoretically sound is to understand perfection. 174 The good itself is the end of every aim, that in which all interests converge. 175 Hence it cannot be defined, as might a special good, in terms of the fulfillment of a set of concrete conditions, but only in terms of the sense or direction of all purposes. 176 The following passage occurs in the "Symposium": "The true order of going or being led by others to the things of love, is to use the beauties of earth as steps along which you mounts upward for the sake of that other beauty, 177 going from one to two, and from two to all fair forms, and from fair forms to fair actions, and from fair actions to fair notions, until from fair notions you arrives at the notion of absolute beauty, and at last knows what the essence of beauty is."

178 There is, then, a "true order of going," and an order that leads from one to many, from thence to forms, from thence to morality, and from thence to the general objects of thought or ‘the ideas’. 179 In the "Republic," where the proper education of the philosopher is in question, it is proposed that one shall study arithmetic, geometry, astronomy, and dialectic. 180 Thus in each case mathematics is the first advance in knowledge, and dialectic the nearest to perfection. Most of Plato's examples are drawn from mathematics. 181 This science replaces the variety and vagueness of the forms of experience with clear, unitary, definite, and eternal natures, such as the number and the geometrical figure. 182 Thus certain individual

things are approximately triangular, but subject to alteration, and indefinitely many. 183 On the other hand the triangle as defined by geometry is the fixed and unequivocal nature or idea which such experiences suggest; and the philosophical mind will at once pass to it from these. 184 But the mathematical objects are themselves not thoroughly understood when understood only in mathematical terms, for the foundations of mathematics are arbitrary. 185 And the same is true of all the so-called special sciences. Even the scientists themselves, says Plato, "only dream about being, but never can behold the waking reality so long as they leave the hypotheses they use unexamined, and are unable to give an account of them. 186 For when a person knows not own first principle, and when the conclusion and intermediate steps are also constructed out of one knows not what, how can you imagine that such a conventional statement will ever become science?"

187 Within the science of dialectics we are to understand the connection and sequences of ideas themselves, in the hope of eliminating every arbitrariness and conventionality within a system of truth that is pure and self-luminous rationality. 188 To this science, which is the great interest of his later years, Plato contributes only incomplete studies and experiments. 189 We must be satisfied with the playful answer with which, in the "Republic," he replies to Glaucon's entreaty 190 that "he proceed at once from the prelude or preamble to the chief strain, and describe that in like manner": "Dear Glaucon, you will not be able to follow me here, though I would do my best."

191 But a philosophical system has been projected. The real is that perfect significance or meaning which thought and every interest suggests, and toward which there is in experience an appreciable movement. 192 It is this significance which makes things what they really are, and which constitutes our understanding of them. 193 In itself it transcends the steps which lead to it; "for God," says Plato, "mingles not with humans." But it is nevertheless the meaning of human life. And this

we can readily conceive. 194 The last word may transform the sentence from nonsense into sense, and it would be true to say that its sense mingles not with nonsense. 195 Similarly the last touch of the brush may transform an inchoate mass of colour into a picture, disarray into an object of beauty; and its beauty mingles not with ugliness. 196 So life, when it finally realises itself, obtains a new and incommensurable quality of perfection in which humanity is transformed into deity. There is frankly no provision for imperfection in such a world. 197 In his later writings Plato sounds his characteristic note less frequently, and permits the ideal to create a cosmos through the admixture of matter. 198 But in his moment of inspiration, the Platonist will have no sense for the imperfect. It is the darkness behind his back, or the twilight through which he passes on his way to the light. 199 He will use even the beauties of earth only "as steps along which he mounts upward for the sake of that other beauty."

200 We have met, then, with two distinct philosophical doctrines which arise from the conception of the ‘absolute’, or the philosopher's peculiar object: 201 the doctrine of the ‘absolute being or substance’, and that of the ‘absolute ideal or good’. Both doctrines are realistic in that they assume reality to be demonstrated or revealed, rather than created, by knowledge. 202 Both are rationalistic in that they develop a system of philosophy from the problem of philosophy, or deduce a definition of reality from the conception, of reality. 203 There remains a third doctrine of the same type-- the philosophy of Aristotle, the most elabourately constructed system of Greek antiquity, and the most potent influence exerted upon the Scholastic Philosophy of the long mediæval period. 204 This philosophy was rehabilitated in the eighteenth century by Leibniz, the brilliant librarian of the court of Hanover. 205 The extraordinary comprehensiveness of Aristotle's philosophy makes it quite impossible to render here even a general account of it. There is scarcely any human discipline that does not to some extent draw upon it. 206 We are concerned only with

the central principles of the metaphysics.

207 Upon the common ground of rationalism and realism, Plato and Aristotle are complementary in temper, method, and principle. 208 Plato's is the genius of inspiration and fertility, Aristotle's the genius of erudition, mastery, and synthesis. 209 In form, Plato's is the gift of expression, Aristotle's the gift of arrangement. Plato was born and bred an aristocrat, and became the lover of the best-- the uncompromising purist; Aristotle is middle-class, and limitlessly wide, hospitable, and patient in his interests. 210 Thus while both are speculative and acute, Plato's mind is intensive and profound, Aristotle's extensive and orderly. 211 It was inevitable, then, that Aristotle should find Plato one-sided. The philosophy of the ideal is not worldly enough to be true.

212 It is a religion rather than a theory of reality. Aristotle, however, would not renounce it, but construe it that it may better provide for Nature and history. This is the significance of his new terminology.

213 Matter, to which Plato reluctantly concedes some room as a principle of degradation in the universe, is now admitted to good standing. 214 Matter or material is indispensable to being as its potentiality or that out of which it is constituted. 215 The ideal, on the other hand, loses its exclusive title to the predicate of reality, and becomes the form, or the determinate nature which exists only in its particular embodiment. 216 The being or substance is the concrete individual, of which these are the abstracted aspects. Aristotle's "form," like Plato's "idea," is a teleological principle. The essential nature of the object is its perfection. 217 It is furthermore essential to the object that it should strive after a higher perfection. With Aristotle, however, the reality is not the consummation of the process, the highest perfection in and for itself, but the very hierarchy of objects that ascends toward it.

218 The highest perfection, or God, is not itself coextensive with being, but the final cause of being-- that on account of which the whole progression of events

takes place. 219 Reality is the development with all of its ascending stages from the maximum of potentiality, or matter, to the maximum of actuality, or God the pure form.

220 To understand the virtue of this philosophy as a basis for the reconciliation of different interests, we must recall the relation between Plato and Spinoza. 221 Their characteristic difference appears to the best advantage in connection with mathematical truth. Both regarded geometry as the best model for philosophical thinking, but for different reasons. 222 Spinoza prized geometry for its necessity, and proposed to extend it. His philosophy is the attempt to formulate a geometry of being, which shall set forth the inevitable certainties of the universe.

223 Plato, on the other hand, prized geometry rather for its definition of types, for its knowledge of pure or perfect natures such as the circle and triangle, which in immediate experience are only approximated. 224 His philosophy defines reality similarly as the absolute perfection.

225 Applied to nature Spinozism is mechanical, and looks for necessary laws, while Platonism is teleological, and looks for adaptation and significance. 226 Aristotle's position is intermediate. With Plato he affirms that the good is the ultimate principle. 227 But this very principle is conceived to govern a universe of substances, each of which maintains its own proper being, and all of which are reciprocally determined in their changes. 228 Final causes dominate Nature, but work through efficient causes. 229 Reality is not pure perfection, as in Platonism, nor the indifferent necessity, as in Spinozism, but the system of beings necessary to the complete progression toward the highest perfection. 230 The Aristotelian philosophy promises, then, to overcome both the hard realism of Parmenides and Spinoza, and also the supernaturalism of Plato.

231 But it promises, furthermore, to remedy the defect common to these two doctrines, the very besetting problem of this whole type of philosophy. 232 That problem, as has been seen, is to

provide for the imperfect within the perfect, for the temporal incidents of Nature and history within the eternal being. 233 Many absolutist philosophers have declared the explanation of this realm to be impossible, and have contented themselves with calling it the realm of opinion or appearance. 234 And this realm of opinion or appearance has been used as a proof of the absolute. 235 Zeno, the pupil of Parmenides, was the first to elabourate what have since come to be known as the paradoxes of the empirical world.

236 Most of these paradoxes turn upon the infinite extension and divisibility of space and time. 237 Zeno was especially interested in the difficulty of conceiving motion, which involves both space and time, and thought himself to have demonstrated its absurdity and impossibility. 238 His argument is thus the complement of Parmenides's argument for the indivisible and unchanging substance. Now the method which Zeno here adopts may be extended to cover the whole realm of Nature and history. 239 We should then be dialectically driven from this realm to take refuge in absolute being. But the empirical world is not destroyed by disparagement, and cannot long lack champions even among the absolutists themselves. 240 The reconciliation of Nature and history with the absolute being became the special interest of Leibniz, the great modern Aristotelian. 241 As a scientist and man of affairs, he was profoundly dissatisfied with Spinoza's resolution of Nature, the human individual, and the human society into the universal being. 242 He became an advocate of individualism while retaining the general aim and method of rationalism.

243 Like Aristotle, Leibniz attributes reality to individual substances, which he calls "monads"; 244 and like Aristotle he conceives these monads to compose an ascending order, with God, the monad of monads, as its dominating goal.

245 "Furthermore, every substance is like an entire world and like a mirror of God, or indeed of the whole world which it portrays, each one in its own fashion; 246

almost as the same city is variously represented according to the various situations of one who is regarding it. 247 Thus the universe is multiplied in some sort as many times as there are substances, and the glory of God is multiplied in the same way by as many wholly different representations of his works."

248 The very "glory of God," then, requires the innumerable finite individuals with all their characteristic imperfections, that the universe may lack no possible shade or quality of perspective.

249 But the besetting problem is in fact not solved, and is one of the chief incentives to that other philosophy of absolutism which defines an absolute spirit or mind. 250 Both Aristotle and Leibniz undertake to make the perfection which determines the order of the hierarchy of substances, at the same time the responsible author of the whole hierarchy. 251 In this case the dilemma is plain. If the divine form or the divine monad be other than the stages that lead up to it, these latter cannot be essential to it, for God is by definition absolutely self-sufficient. 252 If, on the other hand, God is identical with the development in its entirety, then two quite incommensurable standards of perfection determine the supremacy of the divine Nature, that of the whole and that of the highest parts of the whole. 253 The union of these two and the definition of a perfection which may be at once the development and its goal, is the task of absolute idealism.

254 Of the two fundamental questions of epistemology, absolute realism answers the one explicitly, the other implicitly. 255 As respects the source of the most valid knowledge, Parmenides, Plato, Aristotle, Spinoza are all agreed: true knowledge is the work of reason, of pure intellection. 256 Plato is the great exponent of dialectic, or the reciprocal affinities and necessities of ideas. Aristotle is the founder of deductive logic. 257 Spinoza proposes to consider even "human actions and desires" as though he were "concerned with lines, planes, and solids." 258 Empirical data may be the occasion, but cannot be the ground of the

highest knowledge. 259 According to Leibniz, "it seems that necessary truths, such as we find in pure mathematics, and especially in arithmetic and geometry, must have principles whose proof does not depend upon instances, 260 nor, consequently, upon the witness of the senses, although without the senses it would never have come into our heads to think of them."

261 The answers which these philosophies give to the question of the relation between the state of knowledge and its object, divide them into two groups. 262 Among the ancients reason is regarded as the means of emancipation from the limitations of the private mind. "The sleeping turn aside each into a world of one's own," but "the waking"-- the wise people-- "have one and the same world." 263 What the individual knows belongs to the self only in so far as it is inadequate. 264 Hence for Plato the ideas are not the attributes of a mind, but that self-subsistent truth to which, in its moments of insight, a mind may have access. 265 Opinion is "my own," the truth is being. The position of Aristotle is equally clear. "Actual knowledge," he maintains, "is identical with its object."

266 Spinoza and Leibniz belong to another age. Modern philosophy began with a new emphasis upon self-consciousness. 267 In his celebrated argument--"I think, hence I am" (cogito ergo sum)-- Descartes established the independent and substantial reality of the thinking activity. 268 The "I think" is recognised as in itself a fundamental being, known intuitively to the thinker. 269 Now although Spinoza and Leibniz are finally determined by the same motives that obtain in the cases of Plato and Aristotle, they must reckon with this new distinction between the thinker and own object. 270 The result in the case of Spinoza is the doctrine of "parallelism," in which mind is defined as an "infinite attribute" of substance, an aspect or phase coextensive with the whole of being. 271 The result in the case of Leibniz is his doctrine of "representation" and "preëstablished harmony," 272 whereby each monadic substance is in itself an active spiritual entity,

and belongs to the universe through its knowledge of a specific stage of the development of the universe. 273 But both Spinoza and Leibniz subordinate such conceptions as these to the fundamental identity that pervades the whole. 274 With Spinoza the attributes belong to the same absolute substance, and with Leibniz the monads represent the one universe. 275 And with both, finally, the perfection of knowledge, or the knowledge of God, is indistinguishable from its object, God himself. 276 The epistemological subtleties peculiar to these philosophers are not stable doctrines, but render inevitable either a return to the simpler and bolder realism of the Greeks, or a passing over into the more radical and systematic doctrine of absolute idealism.

277 We have met with two general motives, both of which are subordinated to the doctrine of an absolute being postulated and sought by philosophy. 278 The one of these motives leads to the conception of the absolutely necessary and immutable substance, the other to the conception of a consummate perfection. 279 There is an interpretation of life appropriate to each of these conceptions. Both agree in regarding life seriously, in defining reason or philosophy as the highest human activity, 280 and in emphasising the identity of the individual's good with the good of the universe. But there are striking differences of tone and spirit.

281 Although the metaphysics of the Stoics have various affiliations, the Stoic code of morality is the true practical sequel to the Eleatic-Spinozistic view of the world. 282 The Stoic is one who has set own affections on the eternal being. They asks nothing of it for themselves, but identifies the self with it. 283 The saving grace is a sense of reality. The virtuous human is not one who remakes the world, or draws upon it for own private uses; even less one who rails against it, or complains that it has used one ill. 284 You are rather one who recognises that there is but one really valid claim, that of the universe itself. But you not only submits to this claim on account of its superiority; you makes it your own. 285 The

discipline of Stoicism is the regulation of the individual will to the end that it may coincide with the universal will. 286 There is a part of human by virtue of which one is satisfied with what things are, whatever they be. That part, designated by the Stoics as "the ruling part," is the reason. 287 In so far as human seeks to understand the laws and natures which actually prevail, you cannot be discontented with anything whatsoever that may be known to you.

288 "For, in so far as we are intelligent beings, we cannot desire anything save that which is necessary, nor yield absolute acquiescence to anything, save to that which is true: 289 wherefore, in so far as we have a right understanding of these things, the endeavour of the better part of ourselves is in harmony with the order of Nature as a whole."

290 In agreement with this teaching of Spinoza's is the famous Stoic formula to the effect that "nothing can happen contrary to the will of the wise person," who is free through own very acquiescence. 291 If reason be the proper "ruling part," the first step in the moral life is the subordination of the appetitive nature and the enthronement of reason. 292 One who is the self rational-will then recognise the fellowship of all rational beings, and the unitary and beneficent rationality of the entire universe. 293 The highest morality is thus already upon the plane of religion.

294 With Spinoza and the Stoics, the perfection of the individual is reduced to what the universe requires of you. 295 The good person is willing to be whatever you must be, for the sake of the whole with which through reason you are enabled to identify yourself. 296 With Plato and Aristotle the perfection of the individual is commended, that the universe may abound in perfection. 297 The good person is the ideal human-- the expression of the type. And how different the quality of a morality in keeping with this principle! 298 The virtues which Plato enumerates-- temperance, courage, wisdom, and justice-- compose a consummate human nature. He is thinking not of the necessities but of the

possibilities of life. 299 Knowledge of the truth will indeed be the best of human living, but knowledge is not prized because it can reconcile human to own limitations; it is the very overflowing of own cup of life. 300 The youth are to "dwell in the land of health, amid fair sights and sounds; and beauty, the effluence of fair works, will visit the eye and ear, like a healthful breeze from a purer region, and insensibly draw the soul even in childhood into harmony with the beauty of reason."

301 Aristotle's account of human perfection is more circumstantial and more prosaic. "The function of human is an activity of soul in accordance with reason," and his happiness or well-being will consist in the fullness of rational living. 302 But such fullness requires a sphere of life that will call forth and exercise the highest human capacities. 303 Aristotle frankly pronounces "external goods" to be indispensable, and happiness to be therefore "a gift of the gods." 304 The rational human will acquire a certain exquisiteness or finesse of action, a "mean" of conduct; and this virtue will be diversified through the various relations into which you must enter, and the different situations which you must meet. 305 You will be not merely brave, temperate, and just, as Plato would have you, but liberal magnificent, gentle, truthful, witty, friendly, and in all self-respecting or high-minded. 306 In addition to these strictly moral virtues, you will possess the intellectual virtues of prudence and wisdom, the resources of art and science; and will finally possess the gift of insight, or intuitive reason. 307 Speculation will be your highest activity, and the mark of your kinship with the gods who dwell in the perpetual contemplation of the truth.

308 Aristotle's ethics expresses the buoyancy of the ancient world, when the individual does not feel the self oppressed by the eternal reality, but rejoices in it. 309 He is not too conscious of his sufferings to be disinterested in his admiration and wonder. It is this which distinguishes the religion of Plato and Aristotle from that of the Stoics and Spinoza. 310 With both alike, religion consists not in

making the world, but in contemplating it; not in coöperating with God, but in worshipping Him. 311 Plato and Aristotle, however, do not find any antagonism between the ways of God and the natural interests of humans. 312 God does not differ from humans save in His exalted perfection. The contemplation and worship of Him comes as the final and highest stage of a life which is organic and continuous throughout. 313 The love of God is the natural love when it has found its true object.

314 "For you who has been instructed thus far in the things of love, and who has learned to see the beautiful in due order and succession, when you comes toward the end will suddenly perceive a nature of wondrous beauty-- 315 and this, Socrates, is that final cause of all our former toils, which in the first place is everlasting-- 316 not growing and decaying, or waxing and waning; in the next place not fair in one point of view and foul in another, 317 or in the likeness of a face or hands or any other part of the bodily frame, or in any form of speech or knowledge, nor existing in any other being; 318 but beauty only, absolute, separate, simple, and everlasting, which without diminution and without increase, or any change, is imparted to the ever-growing and perishing beauties of all other things."

319 The religion of Spinoza is the religion of one who has renounced the favour of the universe. 320 He was deprived early in life of every benefit of fortune, and set out to find the good which required no special dispensation but only the common lot and the common human endowment. 321 He found that good to consist in the conviction of the necessity, made acceptable through the supremacy of the understanding. 322 The like faith of the Stoics makes of no account the difference of fortune between Marcus the emperor and Epictetus the slave.

323 "For two reasons, then, it is right to be content with that which happens to thee; the one because it was done for thee and prescribed for thee, and in a manner had reference to thee, originally from the most ancient causes spun with thy destiny; 324 and the other

because even that which comes severally to every human is to the power which administers the universe a cause of felicity and perfection, nay even of its very continuance. 325 For the integrity of the whole is mutilated, if thou cuttest off anything whatever from the conjunction and the continuity either of the parts or of the causes. 326 And thou dost cut off, as far as it is in thy power, when thou art dissatisfied, and in a manner triest to put anything out of the way."

THE ACCEPTED CONTENT OF MORALS

George Stuart Fullerton

5 Is there an accepted content of morals? Can we use the expression without going on to ask: Accepted where, when, and by whom?

2 To be sure, certain eminent moralists have inclined to maintain that humans are in substantial agreement in regard to their moral judgments. 3 Joseph Butler, writing in the first half of the eighteenth century, came to the conclusion that, however humans may dispute about particulars, there is an universally acknowledged standard of virtue, 4 professed in public in all ages and all countries, made a show of by all humans, enforced by the primary and fundamental laws of all civil constitutions: namely, justice, veracity, and regard to common good.

5 Sir Leslie Stephen, writing in the latter half of the nineteenth, tells us that "in one sense moralists are almost unanimous; in another they are hopelessly discordant. 6 They are unanimous in pronouncing certain classes of conduct to be right and the opposite wrong. No moralist denies that cruelty, falsity and intemperance are vicious, or that mercy, truth and temperance are virtuous."

7 In other words, these writers would teach us that people are, on the whole, agreed in approving, explicitly or implicitly, some standard of conduct sufficiently definite to serve as a code of morals. 8 But that there is such a substantial agreement among people has not impressed all observers to the same degree. 9 Locke, who wrote before Butler, based his arguments against the

existence of innate moral maxims upon the wide divergencies found among various classes of people touching what is right and what is wrong.

10 The historian, the anthropologist and the sociologist reinforce his reasonings with a wealth of illustration not open to the people of an earlier time. 11 They present us with codes, not a code; with multitudinous standards, not a single standard; with what has been accepted here or there, at this time or at that; and we may well ask ourselves where, amid this profusion, we are to find the one and acceptable code.

WHAT CONSTITUTES SUBSTANTIAL AGREEMENT?

12 To be sure, we may be very generous in our interpretation of what constitutes substantial agreement; 14 we may deny significance to all sorts of discrepancies by relegating them to the unimpressive class of "disputes about particulars." 15 Such an impressionistic indifference to detail may leave us with something on our hands as little serviceable as a composite photograph made from individual objects which have little in common, a blur lacking all definite outline and not recognisable as any object at all. 16 No human can guide own conduct by the common core of many or of all moral codes. Taken in its bald abstraction, it is not a code or anything like a code. 17 Who can walk, without walking in some particular way, in some direction, at some time? Who can mind own manners without being mannerly in accordance with the usages of some race or people?

18 Those who content themselves with enunciating very general moral principles may, it is true, be of no little service to their fellow-humans; but that is only because their fellow-humans are able to supply the details that convert the blur into a picture. 19 Some twenty-four hundred years ago Heraclitus told his contemporaries "to act according to Nature with understanding"; we are often told today that the rule of our lives should be "to do good." 20 Had the ancient Greek not possessed their own notions of what might properly be meant by Nature and

by understanding, did we not ourselves have some rather definite conception 21 of what actions may properly fall under the caption of doing good, such admonitions could not lead to the stirring of a finger. 22 Who would appeal to own physician for advice as to diet, if you expected from no more than the counsel to eat, at the proper hours, enough, but not too much, of suitable food?

23 If, then, we confine our admonitions to the group of abstractions which constitute the universally acknowledged standard of virtue when all the individual differences which characterise different codes have been ignored, 24 we preach what, taken alone, no person can live by, and no community of people has ever attempted to live by. 25 If we leave it to our hearers to drape our naked abstractions with concrete details, each will set to work in a different way. 26 The method of the composite photograph seems unprofitable in attempting to solve the problem of morals.

DOGMATIC ASSUMPTION

27 There is, however, a second way by which the variations which characterise different codes may come to be relegated to a position of relative insignificance. 28 We may assume that our own code is the ultimate standard by which all others are to be judged, and we may set down deviations from it to the account of the ignorance or the perversity of our fellow-people. 29 So regarded, they are aberrations from the normal, and only true code of conduct; interesting, perhaps, but little enlightening, for they can have little bearing upon our conception of what we ought to do.

30 A presumption against this arbitrary assumption that we have the one and only desirable code is suggested the unthinking acceptance of the traditional by those who are lacking in enlightenment and in the capacity reflection. 31 Is it not significant that a contact with new ways of thinking has a tendency, at least, to make people broaden their horizon and to revise some of their views?

32 In other fields, we hope to attain to a capacity for self-criticism. We expect to learn from other people. 33 Why should we, in the sphere of morals, lay claim to the possession of the truth, the whole truth, and nothing but the truth? 34 Why should we refuse to learn from anyone? Such a position seems unreasoning. It puts moral judgments beyond the pale of argument and intelligent discussion. 35 It is an assumption of infallibility little in harmony with the spirit of science. 36 The fact that a given standard of conduct is in harmony with our traditions, habits of thought, and emotional responses, does not prove to other people that it is, not one of a number of accepted codes, 37 but in a quite peculiar sense acceptable, a thing to put in a class by itself-- the class into which each mother puts her own child, as over against other children.

38 Moreover, such an unreasoned assumption of superiority must make one little sympathetic in one's attitude toward the moral life of other peoples. 39 Into the significance of their social organisation, of their customs, their laws, one can gain no insight. 40 Their hopes, their fears, their strivings, their successes and their failures, their approval and disapproval of their fellows, their peace of conscience and their remorse, must leave us cold and aloof.

41 It is not profitable for us to assume at the outset that the differences exhibited in the moral judgments of individuals or of peoples are of minor significance. 42 They are facts to be dealt with in the light of some theory. An ethical theory which ignores them must rest upon a narrow and insecure foundation. 43 It is exposed to assault from many quarters. It may, in default of better means of defence, be compelled to take refuge behind the blind wall of dogmatic assertion. 44 On the other hand, a theory which gives them frank recognition, and strives to exhibit their real significance in the life of the individual and of the race, may be able to show lying among them the golden cord of reason which saves them from the charge of being incoherent facts. 45 It may

even lead us back to a conservatism no longer unreasoning, but rationally defensible and conscious of its proper limits. 46 The blindly conservative person seems to be faced with the alternative of stagnation or revolution. 47 The rationally conservative may regard the development of the moral life as a Pilgrim's Progress, not without its untoward accidents, but, in spite of them, a gradual advance toward a desirable goal.

THE CODES OF COMMUNITIES: JUSTICE

George Stuart Fullerton

6 In view of the existing tendency in the average person, and even in some philosophers, to pass lightly over the diversities exhibited by different codes, 2 it is well to cast a brief preliminary glance at the content of morals as accepted, both by communities of people, and by their more reflective spokes-person, the moralists. Let us first take a look at the codes of communities.

3 We have seen that Butler viewed justice, veracity and regard to common good as virtues accepted among people everywhere. 4 But we may also see, if we look into his pages, that he neglected to point out that there may be the widest divergencies in human's notions of what constitutes justice, veracity and common good. 5 And people differ widely on the score of the degree of emphasis to be laid upon their observance.

6 Take justice. Where people possess a code, written or unwritten, that may properly be called moral, we expect of them the judgment that guilt should be punished. 7 But what shall be accounted guilt? What shall be the measure of retribution? Who shall be fixed upon as guilty?

8 As to what constitutes guilt. We have only to remind ourselves that the Dyak head-hunter is not condemned by his fellows, but is admired; 9 that the fattening and eating of a slave may, in a given primitive community, be accounted no crime; 10 that infanticide has been most widely approved, and that not merely in primitive communities, for Greece and Rome, when they were far from primitive, practiced certain

forms of it with a view to the good of the state; 11 that the holding of a fellow-creature in bondage, and exploiting them for one's own advantage, even under the lash, is no longer a crime in the eye of the law even in the most civilised states. 12 On the other hand, it may be a crime to eat a female opossum. The impressive imperative: Thou shalt not! appears to bear unmistakable reference to time and circumstance.

13 And what is the natural and proper measure of punishment? The ancient and primitive rule of an eye for an eye and a tooth for a tooth suggests the figure of the scales, the impartially meting out to each person of own due.

14 It is obviously a rule that cannot be applied in all cases. One cannot take the tooth of a toothless person, or compel a thievish beggar to restore fruit which has been eaten. 15 We should be horrified were any serious attempt made to make the rule the basis of legislation in any civilised state today, but humans have not always been so fastidious. Approximations to it have been incorporated into the laws of various peoples.

16 But all have modified it to some degree, and the modifications have taken many forms-- the punishment of someone not the criminal, compensation in money or in goods, incarceration, and whatnot. 17 Nor have the modifications been made solely on account of the difficulty of applying the rule baldly stated. Other influences have been at work.

18 Thus, in the famous Babylonian code, the person who struck out the eye of a patrician lost own eye in return, and own tooth answered for the tooth of an equal-- but the rule was not made general. 19 In state after state it has been found just to treat differently the patrician, the plebeian, the slave, the man, the woman, the priest. 20 In the very state to which Butler belonged, benefit of clergy could be claimed, up to relatively recent times, by those who could read. 21 The educated criminal escaped hanging for offences for which own illiterate neighbour had to swing.

22 Nor is there any clear consensus of opinion touching the question of who shall be selected as the bearer of punishment. 23 If a person has injured another unintentionally, shall one be held to make amends? It has seemed just to people that one should. 24 That one person should be made responsible for the misdeeds of another, under the principle of collective responsibility, has commended itself as just to a multitude of minds. 25 Not merely the sins of the fathers, but those of the most distant relations, those of neighbours, of fellow-tribes-people, of fellow-citizens, have been visited upon those whose sole guilt lay in such a connection with the directly guilty parties. 26 This is not a sporadic phenomenon. Among the ancient Hebrews, in Babylonia, in Greece, in the later legislation of Rome, in medieval and even in modern Europe, the principle of collective responsibility has been accepted and has seemed acceptable. 27 Asia, Africa and Oceania have cast votes for it. So have the Americas.

THE CODES OF COMMUNITIES: VERACITY

28 As to veracity: It has undoubtedly been valued to some degree, and with certain limitations, by tribes and nations the most diverse in their degrees of culture. 29 Did people never speak the truth they might well never speak at all. But to maintain that absolute veracity has at all times been greatly valued would be an exaggeration. 30 The lie of courtesy, the clever lie, the lie to the stranger, have been and still are, in many communities both uncivilised and more advanced, not merely condoned, but approved. 31 With the defence which has been made of the doctrines of mental reservation and pious fraud students of church history are familiar. 32 In diplomacy and in war today highly civilised nations find deceptions of many sorts profitable to them, nor are such generally condemned.

33 What modern government does not employ secret service agents, and value them in proportion to the degree of skill with which they manage to deceive their fellows, 34 while limiting the exercise of

professional good faith to their intercourse with their paymaster? 35 The secret service agent of transparent frankness, who could not bear to deceive own neighbour, would not hold the post for a day. You would be a subject for Homeric laughter.

36 Moreover, if the question may be raised: what constitutes justice? May one not equally well ask: what constitutes veracity or its opposite? 37 Where does the silence of indifference shade into purposed concealment, and the latter into what is unequivocally deception? 38 At what point does deception blossom out into the unmistakable lie? One may take advantage of an accidental misunderstanding of what one has said; one may use ambiguous language; one may point instead of speaking. 39 Between going about with a head of glass, with all one's thoughts displayed as in a show-case to every comer, and the settled purpose to deceive by the direct verbal falsification, there is a long series of intermediate positions. 40 The commercial maxim that one is not bound to teach the person with whom one is dealing how to conduct own business, and the lawyer's dictum that the advocate is under no obligation to put the self in the position of the judge, obviously, will bear much stretching.

THE CODES OF COMMUNITIES: THE COMMON GOOD

41 Nor are the facts which confront us less perplexing when we turn to that "regard to the common good" which Butler finds to be acknowledged and enforced by the primary and fundamental laws of all civil constitutions. 42 Whether we look at the past or view the present, whether we study primitive communities or confine ourselves to civilised nations, we see that common good is not, apparently, conceived as the good of all human, however much the words "justice" and "humanity" may be upon people's lips.

43 Has any modern state as yet succeeded in incorporating in its civil constitution such provisions as will ensure to all classes of its subjects any considerable share in the common good? 44 Slaves and animals, said Aristotle, have no

share in happiness, nor do they live after their own choice. 45 The pervading unrest of the modern economic community is due to the widespread conviction that the existing organisation of society does not sufficiently make for the happiness of all. 46 Some states with a high degree of culture have not even made a pretense of having any such aim. They have deliberately legislated for the few.

47 Even where the avowed aim is the common good of all, states have assumed that some must be sacrificed for others. 48 Certain individuals are selected to die in the trenches in the face of the enemy, that others may be guaranteed liberty and the pursuit of happiness. 49 Grotius, the famous jurist of the seventeenth century, has been criticised for holding that a beleaguered town might justly deliver up to the enemy a small number of its citizens in order to purchase immunity for the rest. 50 How far do the cases differ in principle? "Among persons variously endowed," wrote Hegel, "inequality must occur, and equality would be wrong." 51 Commonwealths of many degrees of development have recognised inequalities of many sorts, and have treated their subjects accordingly.

52 "For diet," said Bentham with repellent frankness, "nothing but self-regarding affection will serve." Benevolence he considered a valuable addition "for a dessert." 53 He had in mind the individual, and he did injustice to individuals in certain of their relations. But how do things look when we turn our attention to the relations between states? 54 Does any state actually make it a practice to treat its neighbour as itself? Would its citizens approve of its doing so?

55 The Roman was compelled to formulate a *jus gentium*, a law of nations, to deal with those who held, to him, a place beyond the pale of law as he knew it. 56 Many centuries have elapsed since pagan philosophers taught the brotherhood of man, and since Christian divines began to preach it with passionate fervour. 57 Yet civilised nations today are still seeking to find a *modus-vivendi*, which may put an end to strife and enable them to live together. The

jus-gentium, or its modern equivalent, is, alas! still in its rudiments.

58 To obviate misunderstanding at this point, it is well to state that, in adducing all the above facts, I do not mean to argue that it is abnormal and an undesirable thing that the scales of justice should, at times, be weighted in divers ways. 59 I am not maintaining that the distribution of common good should proceed upon the principle of strict impartiality.

60 What is possible and is desirable in this field is not something to be decided off-hand. 61 But the facts suffice to illustrate the truth that the discrepancies to be found in the codes of different communities can scarcely be dismissed as unimportant details. They are something far too significant for that.

THE CODES OF THE MORALISTS

George Stuart Fullerton

7 If, from the codes, or the more or less vague bodies of opinion, which have characterised different communities, we turn to the moralists, we find similar food for thought.

2 But who are the moralists? Can we put into one class those who preach a short-sighted selfishness or a calculating egoism and those who urge upon us the law of love? 3 Those who recommend a contempt of humankind, and those who inculcate a reverence for humanity? 4 Those who incline to leave us to our own devices, telling us to listen to conscience, and those who draw up for us elabourate sets of rules to guide conduct? 5 The histories of ethics are rather tolerant in herding together sheep and goats. And not without reason. 6 Those whom they include have been in a sense the spokes-person of their fellows. Their words have found an echo in the souls of many. 7 They are concerned with a rule of life, and their rule of life, such as it is, rests upon some principle which has impressed people as being not wholly unreasonable.

8 In taking a glance at what they have to offer us, I shall not go far afield, and shall exercise a brevity compatible with the purpose of mere illustration. 9 To the

moralists of ancient Greece, and, to a lesser degree, to those of the Roman Empire, to the Christian teachers who succeeded to their heritage in the centuries which followed, 10 and to the more or less independent thinkers who made their appearance after the Reformation, we can trace our ethical pedigree. 11 For our purpose we need seek no wider field. Here we may find sufficiently notable contrasts of opinion to disturb the dogmatic slumber of even an inert mind. 12 The most cursory glance makes us inclined to accept with some reserve Stephen's claim that "the difference between different systems is chiefly in the details and special application of generally admitted principles."

EPICUREAN AND STOIC

13 Thus, Aristippus of Cyrene advised people to grasp the pleasure of the moment rather than to await the more uncertain pleasure of the future; 14 but he also counselled, for prudential reasons the avoidance of a conflict with the laws. 15 Such advice takes cognisance of the self-love of the individual, and is not self-love reasonable?

16 Nevertheless, such advice might be given by a discouraged criminal of a reflective turn of mind, on release from prison, to a comrade not yet chastened by incarceration. 17 Epicurus praises temperance and fortitude, but only as measures of prudence. 18 He praises justice, but only in so far as it enables us to escape harm, and frees us from that dread of discovery that haunts the steps of the evil-doer. 19 His more specific maxims, do not fall in love with a woman, become the father of a family, or, generally, go into politics, smack strongly of the rule of life recommended to Feuillet's hero, Monsieur de Camors, by his worldly-wise and cynical father.

20 Contrast with these men the Stoics, whose rule of life was to follow Nature, and to eschew the pursuit of pleasure. Human's nature, said Epictetus, is social; wrongdoing is antisocial; affection is natural.

21 Said Marcus Aurelius, it is characteristic of the rational soul for a person to love own

neighbour. 22 The cautious bachelor imbued with Epicurean principles would find strange and disconcerting the Stoic position touching citizenship: 23 "My nature is rational and social; and my city and country, so far as I am Antoninus, is Rome, but so far as I am a man, it is the world. The things then which are useful to these cities are alone useful to me."

PLATO; ARISTOTLE; THE CHURCH

24 No more famous classification of the virtues-- those qualities of character which it is desirable for a human to have, and which determine your doing what it is desirable that you should do-- 25 has ever been drawn up than that offered us by Plato: Wisdom, Courage, Temperance and Justice. 26 It is interesting to lay beside it the longer list drawn up by Aristotle, and to compare both with that which commended itself to the mind of the mediaeval church-person.

27 With Aristotle, the virtues are made to include:

Wisdom
High-mindedness
Justice
Ambition
Courage
Gentleness
Temperance
Friendliness
Liberality
Truthfullness
Magnificence
Decorous Wit

28 and it is suggested that, although scarcely a virtue, a sense of shame is becoming in youth.

29 We find the Christian teachers especially recommending:

Obedience
Patience
Benevolence
Purity
Humility
Alienation from the "World"
Alienation from the "Flesh"

30 and their lists of the "deadly sins" they select from the following:

Pride
Arrogance
Anger
Gluttony
Unchastity
Envy
Vain-Glory
Gloominess
Languid Indifference.

31 Could there be a more striking contrast than that between the mediaeval code and those of the great Greek thinkers? 32 Plato recommended as virtues certain general characteristics of character much admired by the Greek of his day. 33 Aristotle accepted them and added to them. He has painted much more in detail the gifts and graces of a well-born and well-situated Greek gentleman as he conceived him. 34 The personage would cut a sorry figure in the role of a mediaeval saint; the mediaeval saint would wear a tarnished halo if endowed with the Aristotelian virtues.

35 The one ideal, the Greek, breathes an air of self-assertion; the other one of self-abnegation. 36 Benevolence, Purity, Humility and Unworldliness are not to be found in the former; Justice, Courage and Veracity appear to be missing in the latter. 37 Wisdom, insight, has given place to the Obedience appropriate to a person clearly conscious of a Law, not human-made, to which human feels the self to be subject.

38 Indeed, the discrepancy between the ideals is such that Aristotle's virtuously high-minded human would have been conceived by the mediaeval churchman to be living in deadly sin, as the very embodiment of pride and arrogance. 39 We find them portrayed as neither seeking nor avoiding danger, for there are few things about which they cares; as ashamed to accept favours, since that implies inferiority; 40 as sluggish and indifferent except when stimulated by some great honour to be gained or some great work to be performed; 41 as frank, for this is characteristic of the person who despises others; as admiring little, for nothing is great to them. 42 Their pride prevents them from harbouring resentment, from seeking praise, and from praising others. This Nietzschean hero would attract attention upon any stage: 43 "The step of the high-minded human is slow, their voice deep, and their language stately, for you who feels anxiety about few things is not apt to be in a hurry; and you who thinks highly of nothing is not vehement."

44 To be sure, virtues not on a given list may be found in, or read into, some of the writings of the

human who presents it. 45 It would be absurd to maintain that the mediaeval churchman had no regard for justice, courage and veracity, as they would define them, or that Plato and Aristotle were wholly deaf to the claims of benevolence. 46 Nevertheless, the variations in the emphasis laid on this virtue or on that, or in the conception of what constitutes this virtue or that, may yield ideals of character and of conduct which bear but a slight family resemblance. 47 Imagine St. Francis of Assisi lowering his voice, slowing his step, and cultivating "high- mindedness," or striving to make himself a pattern of decorous wit.

LATER LISTS OF THE VIRTUES

48 The codes proposed by the moralists of a later time are numerous and widely scattering. It is impossible to do justice to them in any brief compass. 49 A very few instances, selected from among those most familiar to English readers, must suffice to indicate the diversity of their nature.

50 Hobbes deeply concerned to discover some *modus vivendi* which should put a check upon strife between human and own fellow-human, 51 and save us from a life "solitary, poor, nasty, brutish and short," recommends among other virtues:

Justice
Equity
Requital of benefits
Sociability

52 A moderate degree of forgiveness.

The avoidance of pride and arrogance.

53 Locke, who believes that moral principles must be intuitively evident to one who contemplates the nature of God and the relations of humans to Him and to each other, thinks it worthwhile to set down such random maxims as:

54 No government allows absolute liberty.

Where there is no property there is no injustice.

All humans are originally equal.

Humans ought not to harm one another.

Parents have a right to control their children.

55 Hume, whose two classes of virtues comprise the qualities immediately agreeable or useful to ourselves and those immediately agreeable or useful to others, offers us an extended list. 56 He puts into the first class:

Discretion
Caution
Enterprise
Industry
Frugality
Economy
Good Sense, etc.
Temperance
Sobriety
Patience
Perseverance
Considerateness
Secrecy
Order, etc.

57 In the second class he includes:

Benevolence
Justice
Veracity
Fidelity
Politeness
Wit
Modesty
Cleanliness.

58 Manifestly, the lists may be indefinitely prolonged. Why not add to the first-class the pachydermatous indifference to rebuffs which is of such service to the social climber, and, to the second, taste in dress and the habit of not repeating stories?

59 Thomas Reid lays stress upon the deliverances of the individual conscience, when consulted in a quiet hour. 60 Nevertheless he proposes five fundamental maxims:

We ought to exercise a rational self-love, and prefer a greater to a lesser good.

We should follow Nature, as revealed in the constitution of human.

We should exercise benevolence.

Right and wrong are the same for all in the same circumstances.

We should venerate and obey God.

61 With such writers we may contrast the Utilitarians and the adherents of the doctrine of Self-realisation, who lay little stress upon lists of virtues or duties, but aim, respectively, at the greatest happiness of the greatest number, 62 and at the harmonious development of the faculties of human, regarding as virtues such qualities of character as make for the attainment, in the long run, of the one or the other of these ends.

THE STRETCHING OF MORAL CONCEPTS

63 The instances given suffice to show that the moralists speak with a variety of tongues. The code of one age is apt to seem strange and foreign to the people of another. 64 Even where there is apparent agreement, a closer scrutiny often reveals that it has been attained by a process of stretching conceptions. 65 Take for example the so-called "cardinal" virtues dwelt upon by Plato. The Stoics, who made use of his list, changed its spirit. 66 Cicero stretches justice so as to make it cover a watery benevolence. St. Augustine finds the cardinal virtues to be different aspects of Love to God. 67 The great scholastic philosopher of the thirteenth century, St. Thomas, places in the first rank the Christian graces of Faith, Hope and Charity, 68 but still finds it convenient to use the Platonic scheme in ordering a list of the self-regarding virtues taken from Aristotle. 69 Thus may the pillars of a pagan temple be utilised as structural units in, or embellishments of, a Christian church.

70 Our own age reveals the same tendency. Thomas Hill Green, the Oxford professor, follows Plato. But with him we find wisdom stretched to cover artistic creation; 71 we see that courage and temperance have taken on new faces; and justice appears to be able to gather under its wings both benevolence and veracity. 72 A still wider divergence from the original understanding of the cardinal virtues is that of Dewey, who conceives of them as "traits essential to all morality." 73 He treats, under temperance, of purity and reverence; he makes courage synonymous with persistent vigour; he extends justice so as to include love and sympathy; he transforms wisdom into conscientiousness.

74 This variation in the content of moral concepts may be illustrated from any quarter in the field of ethics. 75 Cicero's circumspect "benevolence" advances the doctrine that "whatever one can give without suffering loss should be given even to an entire stranger." 76 Among such obligations he reckons: to prohibit no one from drinking at a stream

of running water; to permit anyone who wishes to light fire from fire; to give faithful advice to one who is in doubt; 77 which things, as he naively remarks, "are useful to the receiver and do no harm to the giver."

78 Compare with this the admonition to love one's neighbour as oneself; Sidgwick's "self-evident" proposition that "I ought not to prefer my own lesser good to the greater good of another;" 79 Bentham's utilitarian formula, "everybody to count for one, and nobody for more than one." The admonition, "be benevolent," may mean many things.

THE REFLECTIVE MIND AND THE MORAL CODES

80 Even the cursory glance we have given above to the moral codes of different communities and those proposed by individual moralists must suffice to bring any thoughtful human to the consciousness that they differ widely among themselves, 81 and that the differences can scarcely be dismissed as insignificant. 82 A little reflection will suffice to convince him, furthermore, that to treat all other codes as if they were mere pathological variations from his own is indefensibly dogmatic.

83 On the other hand, the differences between codes should not be unduly emphasised. The core of identity is there, and, although in its bald abstractness it is not enough to live by, it is vastly significant, nevertheless. 84 If there were not some congruity in the materials, they would never be brought together as the subject of one science. 85 Unless "good," "right," "obligation," "approval," etc., or the rudimentary conceptions which foreshadow them in the mind of the most primitive human beings, had a core of identity which could be traced in societies the most diverse, 86 there would be no significance in speaking of the enlightened morality of one people and the degraded and undeveloped morality of another. 87 There could be no history of the development of the moral ideas. Collections of disparate and disconnected facts do not constitute a science, nor are

they the proper subject of a history.

88 As a matter of fact, we all do speak of degraded moral conceptions, of a perverted conscience, of a lofty morality, of a fine sense of duty; 89 we do not hesitate to compare, i. e., to treat as similar and yet dissimilar, the customs, laws and ethical maxims of different ages and of different races. 90 This means that we have in our minds some standard, perhaps consciously formulated, perhaps dimly apprehended, according to which we rate them. 91 The unreflective human is in danger of taking as this standard one's own actual code, such as it is; of accepting, together with such elements of reason as it may contain, 92 the whole mass of one's inherited or acquired prejudices; the more reflective human will strive to be more rationally critical.

THE DOGMATISM OF THE NATURAL HUMAN

George Stuart Fullerton

8 In morals and in politics it seems natural for human to be dogmatic, to take a position without hesitation, to defend it vehemently, to maintain that others are in the wrong.

2 This is not surprising. We are born into a moral environment as into an all-embracing atmosphere. From the cradle to the grave, we walk with our heads in a cloud of exhortations and prohibitions. 3 From our earliest years we have been urged to make decisions and to act, and we have been furnished with general maxims to guide our action. 4 When, therefore, we approach the solution of a moral problem, we do not, as a rule, acutely feel our fitness to solve it, even though we may be judged quite unfit by others.

5 This unruffled confidence in one's possession of an adequate supply of indubitable moral truth may be found in people who differ widely in their degree of intelligence and in the extent of their information. 6 Some

individuals seem born to it. We may come upon it in the ethical philosopher; we may meet it in the person of science, who knows that it has taken one a quarter of a century to fit the self to be an authority in matters chemical or physical, 7 but who wanders in own hours of leisure into the field of ethics and has no hesitation in proposing radical reforms. 8 But it is more natural to look for the unwavering confidence which knows no questionings among persons of restricted outlook, who have been brought into contact with but one set of opinions. 9 It is characteristic of the child, of the uncultivated classes in all communities, of whole communities primitive in their culture and relatively unenlightened.

THE AWAKENING

10 Manifestly, even the beginnings of ethical science are an impossibility where such a spirit prevails. 11 Where there are no doubts, no questionings, there can be no attempt at rational construction.

12 Fortunately for the cause of human enlightenment there are forces at work which tend to arouse people from this state of lethargy. 13 Horizons are broadened, new ideas make their appearance, there is a conflict of authorities, the birth of a doubt, and, finally, a more or less articulate appeal to Reason.

14 Even a child is capable of seeing that paternal and maternal injunctions and reactions are not wholly alike, and it sets them off against each other. Nor have all the children in the home precisely the same nature.

15 One is temperamentally frank and open, but unsympathetic; another is affectionate, and prone to lying as the sparks fly upward. 16 The virtues and vices are not spontaneously arranged in the same order of importance by children, and differences of opinion may arise. 17 Nor does it take the child long to discover that the law of its own home is not identical with that of the house next door. 18 At school the experience is repeated on a larger

scale; many homes are represented, and, besides that, two codes of law claim allegiance, the code of the schoolboy and that of the master. They may be by no means in accord.

19 And when, in college, the student for the first time seriously addresses the self to the task of the study of ethics as science, one comes to it by no means wholly unprepared. 20 You has had rather a broad experience of the contrasts which obtain between different codes. You are familiar with the code of the home, of the school, of the social class, of the religious community, of the civil community. 21 There sit on the same benches with you the sensitively conscientious student who doubts whether it is a permissible deception of one's neighbour to apply a patch to an old garment so skillfully that it will escape detection; 22 the sporting character who takes it to be the mutual understanding among people that truth shall not be demanded of those who deal in horses and dogs; 23 the youth from Texas who claims that the French philosopher, Janet, cannot be an authority on morals, since he asserts that he who cheats at cards must feel a burning shame. 24 With the ethics of the ancient Hebrews, of the Greeks, of the Romans, our young moralist has had the opportunity to acquire some familiarity, and he can compare them, if he will, with the Christian ethics of his own day. 25 He knows something of history and biography; he has read books of travel, and has some acquaintance with the manners and customs of other peoples. 26 Were he given to reflection, it ought not to surprise him to find a Portuguese sea-cook maintaining that it is wrong to steal, except from the rich; 27 or to learn that a Wahabee saint rated the smoking of tobacco as the worst possible sin next to idolatry, while maintaining that murder, robbery, and such like, were peccadilloes which a merciful God might properly overlook.

28 Material for reflection he has in abundance-- and he often remains relatively dogmatic and unplagued by doubt. 29 But only relatively so; and only so long as the claims of conflicting authorities are not

forced upon his attention, rendered importunate in the light of discussion, made so familiar as to seem real and substantial. 30 It is the tendency of the widening of the horizon to arouse people to reflection, to stimulate to criticism. From such criticism the science of ethics has its birth.

31 What is true of the individual is true of people in the mass. The blind life of social classes long laid in chains by custom and tradition may come to be illuminated by new ideas, 32 and passive acquiescence may give way to active participation in social endeavour. Nor can primitive peoples remain wholly primitive except in isolation. 33 With the increased intercourse between races and peoples, humans are brought to a clear consciousness that the accepted in morals is manifold and diverse; 34 the next step is to question whether it is, in any given instance, of unquestionable authority; thus do people become ripe for the search for the acceptable.

ETHICAL METHOD

George Stuart Fullerton

9 Professor Henry Sidgwick has defined a method of ethics as "any rational procedure by which we determine what is right for individual human beings to do, or to seek to realise by voluntary action."

2 He points out that many methods are natural and are habitually used, but claims that only one can be rational. 3 By which he means that the several methods of determining right conduct urged by the different schools of the moralists must be reconciled, or all but one must be rejected.

4 In this chapter I shall not discuss in detail the schools of the moralists and the specific methods which characterise them. 5 I am here concerned only with the general distinction between the scientific methods of deduction and induction, and its bearing upon ethical investigations.

6 How do we discover that, in an isosceles triangle, the sides which subtend the equal angles are equal? 7 We do not go about collecting the opinions of

individuals upon the subject, nor do we consult the records of other peoples, past or present. 8 We do not measure a great number of triangles and arrive at our conclusion after a calculation of the probable error of our measurements. 9 The appeal to authorities does not interest us; that measurements are always more or less inaccurate, and that all actual triangles are more or less irregular, we freely admit, but we do not regard such facts as significant. 10 We use a single triangle as an illustration, and from what is given in, or along with, that individual instance, we deduce certain consequences in which we have the highest confidence. 11 Here we follow the method of deduction. We accept a "given," with its validity we do not concern ourselves; our aim is the discovery of what may be gotten out of it.

12 In the inductive sciences the individual instance has an importance of quite a different sort. 13 It is not a mere illustration, unequivocally embodying a general truth to which we may appeal directly, treating the instance as a mere vehicle, in itself of little significance. 14 Individual instances are observed and compared; uniformities are searched for; it is sought to establish general truths, not directly evident, but whose authority rests upon the particular facts that have been observed and classified.

15 It is a commonplace of logic that both induction and deduction may be employed in many fields of science. 16 We may attain by inductive inquiry to more or less general truths, which we no longer care to call in question, and which we accept as a "given," to be exploited and carried out in its consequences. 17 Indeed, we need not betake ourselves to science to have an illustration of this method of procedure. 18 In everyday life people have maxims by which they judge of the probable actions of their fellow-people and in the light of which they direct their dealings with them. 19 Such maxims as that people may be counted upon to consult their own interests have certainly not been adopted independently of an experience of what, on particular occasions, people have shown

themselves to be. 20 But, once adopted, they may be treated as, for practical purposes, unquestionable; people are concerned to apply them, not to substantiate them. 21 In so far, people reason from them deductively and pass from the general rule to the particular instance.

THE AUTHORITY OF THE "GIVEN"

22 Obviously the "given," in the sense indicated, may possess, in certain cases, a very high degree of authority, and, in others, a very low degree.

23 In the case of the mathematical truth referred to above, people do not, in fact, find it necessary to call in question the "given," 24 though they may be divided in their notions touching the general nature of mathematical evidence and whence it draws its apparently indisputable authority. 25 In certain of the inductive sciences, as in mechanics, physics and chemistry, generalisations have been attained in which even the critical repose much confidence. 26 In other fields people are constantly making general statements which are promptly contradicted by their fellows, and are drawing from them inferences the justice of which is in many quarters disallowed. 27 There are axioms and axioms, maxims and maxims. 28 The confidence felt by a given individual in a particular "given" does not guarantee its acceptance by all people of equal intelligence. 29 Where, however, the evidence upon which a disputed "given" is based is forthcoming, there is, at least, ground for rational discussion.

30 Not a few famous writers have treated moral truths as analogous to mathematical. 31 To take here a single instance. Sidgwick, in his truly admirable work on "The Methods of Ethics," maintains that 32 "the propositions, 'I ought not to prefer a present lesser good to a future greater good,' and 'I ought not to prefer my own lesser good to the greater good of another,' 33 do present themselves as self-evident; as much e.g. as the mathematical axiom that 'if equals be added to equals the wholes are equals.'"

34 But it is one thing to claim that we are in possession of a "given" with ultimate and indisputable authority; it is another to convince people that we really do possess it. 35 Locke's efforts at deduction fall lamentably short of the model set by Euclid. 36 "Professor Sidgwick's well-known moral axiom, 'I ought not to prefer my own lesser good to the greater good of another,' 37 would," writes Westermarck, "if explained to a Fuegian or a Hottentot, be regarded by him, not as self-evident, but as simply absurd; nor can it claim general acceptance even among ourselves. 38 Who is that 'Another' to whose greater good I ought not to prefer my own lesser good? A fellow-countryman, a savage, a criminal, a bird, a fish-- all without distinction?" 39 To Bentham's "everybody to count for one and nobody for more than one" may be opposed Hartley's preference of benevolent and religious persons to the rest of humankind.

40 The fact that people eminent for their intellectual ability and for the breadth of their information are, in morals, inclined to accept, as ultimate, principles not identical, 41 and thus to found different schools, would seem to indicate that, to one who aims at treating ethics as a science, principles, as well as the deductions from them, should be objects of closest scrutiny. 42 They should not be taken for granted. The history of ethical theory appears to make it clear that the "given" of the moralist is not of the same nature as that of the geometer.

43 The ethical philosopher cannot, hence, confine the self to developing deductively the implications of some principle or principles assumed without critical examination. 44 One must establish the validity even of own principles. This we should bear in mind when we approach the study of the different ethical schools.

HOW THE MORALIST SHOULD PROCEED

George Stuart Fullerton

10 The above reflections on method suggest the materials of which the moralist should avail the

self in rearing the edifice of own science.

2 (1) Evidently you should reflect upon the moral judgments which you finds in yourself, the moral being with whom you are best acquainted. 3 You should endeavour to render consistent and luminous moral judgments which, as you finds, have too often been inconsistent and more or less blind.

4 (2) You should take cognisance of your own setting-- of the social conscience embodied in the community in which you lives.

5 (3) And since, as we have seen, the significance, either of the individual conscience, or of the social conscience revealed in custom, law and public opinion, 6 can hardly become apparent to one who does not bring within own horizon many consciences individual and social, you should enlarge your view so as to include such. 7 The moralists, in our day, show an increasing tendency to pay serious attention to this mass of materials. 8 They do not confine their attention to the moral standard which this person or that has accepted as authoritative for you, nor to that accepted as authoritative in a given community. 9 They study human-- human in all stages of own development and in material and social settings the most diverse.

10 (4) Nor should the student of ethics overlook the work which has been done by those moralists who have gone before you. 11 You who has studied descriptive anatomy is aware of the immense service which has been done you by the unwearied observations of your predecessors; 12 observations which have been put on record, and which draw your attention to numberless details of structure that would, without such aid, certainly escape your attention. 13 Ethics is an ancient discipline. It has fixed the attention of acute minds for many centuries. 14 You who approaches the subject naively, without an acquaintance with the many ethical theories which have been advanced and the acute criticisms to which they have been subjected, will almost certainly say what someone has said before, and said, perhaps, much better. 15 The valour of ignorance will involve you in ignominious defeat.

16 (5) It is evident that the moralist must make use of materials offered you by workers in many other fields of science. 17 The biologist may have valuable suggestions to make touching the impulses and instincts of human.

18 The psychologist treats of the same, and exhibits the work of the intellect in ordering and organising the impulses. They studies the phenomena of desire, will, habit, the formation of character. 19 The anthropologist and the sociologist are concerned with the codes of communities and with the laws of social development. 20 The fields of economics, politics and comparative jurisprudence obviously march with that cultivated by the student of ethics.

THE PHILOSOPHER AS MORALIST

21 In all these sciences at once it is not possible for the moralist to be an adept. 22 The mass of the material they furnish is so vast that the ethical writer who starts out to master it in all its details may well dread that one may be overcome by senility before one is ready to undertake the formulation of an ethical theory.

23 It does not follow, however, that you should leave to those who occupy themselves professionally with any of these fields the task of framing a theory of morals. 24 You must have sufficient information to be able to select with intelligence what has some important bearing upon the problem of conduct, 25 but there are many details into which you need not go. It is well to note the following points:

26 (1) A multitude of details may be illustrative of a comparatively small number of general principles. It is with these general principles that the moralist is concerned. 27 The anthropologist may regard it as own duty to spend much labour in the attempt to discover why this or that act, this or that article of food, happens in a given community to be taboo to certain persons. 28 The student of ethics is not bound to take up the detailed investigation of such matters. 29 Human nature, in its general constitution, is much the same in different races and peoples. The influence of

environment is everywhere apparent. 30 There are significant uniformities to be discovered even by one who has a limited amount of detailed information. 31 "Those who come after us will see nothing new," said Antoninus, "nor have those before us seen anything more, 32 but in a manner you who is forty years old; if you have any understanding at all, has seen by virtue of the uniformity which prevails all things which have been and all that will be." 33 Which is, to be sure, an overstatement of the case, but one containing a germ of truth.

34 (2) We find, by looking into their books, that people most intimately acquainted with the facts of the moral life as revealed in different races and peoples may differ widely in the ethical doctrine which they are inclined to base upon them. 35 Not all people, even when endowed with no little learning, are gifted with the clearness of vision which can detect the significance of given facts; nor are all equally capable of weaving relevant facts into a consistent and reasonable theory. 36 The keenness and the constructive genius of the individual count for much. And breadth of view counts for much also. 37 We have seen that ethics touches many fields of investigation, and the philosopher is supposed, at least, to let own vision range over a broad realm, and to grasp the relations of the different sciences to each other. 38 You are, moreover, supposed to be trained in reflective analysis, and of this ethical theory appears to stand in no little need.

39 (3) Finally, the mere fact that ethics has for so many centuries been regarded as one of the disciplines falling within the domain of the philosopher is not without its significance. 40 One may deplore the tendency to base ethics upon this or that metaphysical doctrine, and desire to see it made an independent science; 41 and yet one may be compelled to admit that it is not easy to comprehend and to estimate the value of many of the ethical theories which have been evolved in the past, without having rather an intimate acquaintance with the history of philosophy. 42 The ethical teachings of Plato,

of Aristotle, of St. Thomas, of Kant, of Hegel, of Green, lose much of their meaning when taken out of their setting. 43 The history of ethical theory is blind when divorced from the history of philosophy, and with the history of ethical theory the moralist should be acquainted.

44 The philosopher has no prescriptive right to preempt the field of ethics. Many people may cultivate it with profit. 45 Nevertheless, you, too, should cultivate it, not independently and with a disregard of what has been done by others, but in a spirit of hearty cooperation, thankfully accepting such help as is offered you by your neighbours.

THE APPEAL TO REASON

George Stuart Fullerton

11 The proper aim of the scientific study of ethics appears to be suggested with sufficient clearness by what has been said in the chapters on the accepted content of morals.

2 Where individuals take up unreflectively the maxims which are to control their conduct, human life can scarcely be said to be under the guidance of reason. 3 Where, moreover, the codes of individuals clash with each other or with the social conscience of their community, and where the codes of different communities are disconcertingly diverse, playful concerted action with a view to the control of conduct appears to be impracticable. 4 Historical accident, blind impulse and caprice, cannot serve as guides for a rational creature seeking to live, along with others, a rational life.

5 "The aim of ethics," says Sidgwick, "is to render scientific i.e., true, and as far as possible systematic-- 6 the apparent cognitions that most humans have of the rightness or reasonableness of conduct, whether the conduct be considered as right in itself, or as the means to some end conceived as ultimately reasonable." 7 The use here of the word "cognitions" calls our attention to the fact that, when people say, "this is right, that is wrong," they mean no more than, "this I like, that I do not like"; 8 and the use of the word "apparent" indicates that the

judgments expressed may be approved by the person who makes them, and yet be erroneous. 9 The appeal is to an objective standard; there is a demand for proof.

10 That most people recognise, in some cases dimly, in some cases clearly and explicitly, that the appeal to such a standard is justifiable, can scarcely be denied. 11 Between "I choose" and "I ought to choose," between "the community demands," and "the community ought to demand," people generally recognise a distinction when they have attained to a capacity for reflection.

12 It has, however, been denied that the appeal is justifiable, and denied by no mean authority. 13 "The presumed objectivity of moral judgments," writes Westermarck, "being a chimera, there can be no moral truth in the sense in which this term is generally understood. 14 The ultimate reason for this is, that the moral concepts are based upon emotions, and that the contents of an emotion fall entirely outside the category of truth. 15 But it may be true or not that we have a certain emotion, it may be true or not that a given mode of conduct has a tendency to evoke in us moral indignation or moral approval. 16 Hence a moral judgment is true or false according as its subject has or has not that tendency which the predicate attributes to it. 17 If I say that it is wrong to resist evil, and yet resistance to evil has no tendency whatever to call forth in me an emotion of moral disapproval, then my judgment is false." 18 The conclusion drawn from this is that there are no general moral truths, and that "the object of scientific ethics cannot be to fix rules for human conduct"; it can only be "to study the moral consciousness as a fact."

THE APPEAL TO REASON JUSTIFIED

19 The words of so high an authority should not be passed over lightly. One is impelled to seek for their proper appreciation and their reconciliation with the judgment of other moralists. 20 Such can be found, I think, by turning to two truths dwelt upon in

what has preceded: the truth that the moralist should not assume that you are possessed of a "given" analogous to that of the geometer--a standard in no need of criticism; 21 and the equally important truth that the moralist cannot hope to frame a code which will simply replace the codes of individual communities and will prescribe the details of human conduct while ignoring such codes altogether.

22 But it does not seem to follow that, because the moralist may not set up an arbitrary code of this sort, you are also forbidden to criticise and compare moral judgments, 23 to arrange existing codes in a certain order as lower and higher, to frame some notion of what constitutes progress. 24 You may hold before yourself, in outline, at least, an ideal of conduct, and not one taken up arbitrarily but based upon the phenomena of the moral consciousness as you have observed them. 25 And in the light of this ideal you may judge of conduct; your appeal is to an objective standard.

26 Thus, you who says that it is false that it is right to reduce to slavery prisoners taken in war may, if you be sufficiently unreflective, have no better reason for your judgment than a feeling of repugnance to such conduct. 27 But, if you have risen to the point of taking broad views of people and their moral codes, you may very well assert the falsity of the statement even when you feels no personal repugnance to the holding of certain persons as slaves. 28 Your appeal is, in fact, to such a standard as is above indicated, and your condemnation of certain forms of conduct is based upon their incompatibility with it.

29 Hence, a person may significantly assert that certain conduct is objectively desirable, although it may not be desired by yourself or by your community.

30 You may judge a thing to be wrong without feeling it to be wrong. Whether anything would actually be judged to be wrong, if no one ever had any emotions, is a different question. 31 With it we may class the question whether anything would be judged to be wrong if no one were possessed of even a spark of reason. 32 There is small choice between having

nothing to see and not being able to see anything.

32 An appeal, thus, from the actual to the ideal appears to be possible. 33 And, since the natural human, unenlightened and unreflective, is not more inclined to show the self to be a reasonable being in the sphere of morals than elsewhere, it seems that there is no little need of ethical science.

34 Its aim is to bring about the needed enlightenment. Its value can only be logically denied by those who maintain seriously that it is easy to know what it is right to do. Do people really hold this, if they are thoughtful?

HUMAN'S NATURE

George Stuart Fullerton

THE BACKGROUND OF ACTIONS

12 In estimating human actions we take into consideration both the doer and the circumstances under which the deed was done. 2 Actions may be desirable or undesirable, good or bad, according to their setting. How shall we judge of the blow that takes away human life? 3 It may be the involuntary reaction of a person startled by a shock; it may be a motion of justifiable self-defence; it may be one struck at the command of a superior and in the defence of one's country; it may be the horrid outcome of cruel rapacity or base malevolence.

4 Nor are the emotions, torn out of their context, more significant than actions without a background. 5 They are mental phenomena to be observed and described by the psychologist; 6 to the moralist they are, taken alone, as unmeaning as the letters of the alphabet, but, like them, capable in combination of carrying many meanings. 7 Anger, fear, wonder, and all the rest are, as natural emotions, neither good nor bad; they are colours, which may enter into a picture and in it acquire various values.

8 In morals, when people have attained to the stage of enlightenment at which moral estimation is a possible process, they always consider emotions, intentions, and actions in the light of their background. 9 We do not demand a moral life of the brutes; we do not look for it in the

intellectually defective and the emotionally insane; 10 nor do we expect a savage caught in the bush to harbour the same emotions, or to have the same ethical outlook, as the missionary with whom we may confront.

11 The concepts of moral responsibility, of desert, of guilt, are emptied of all significance, when we lose sight of the nature, inborn or acquired, of the creature haled before the bar of our judgment, and of the environment, 12 which on the one hand, impels you to action, and, on the other, furnishes the stage upon which the drama of your life must be played out to the end.

13 Hence, you who would not act as the creature of blind impulse or as the unthinking slave of tradition, but would exercise a conscious and intelligent control over your conduct, seems compelled to look at your life and its setting in a broad way, 14 to scrutinise with care both the nature of human and the environment without which that nature could find no expression. 15 When you does this, you only does more intelligently what people generally do instinctively and somewhat at haphazard. 16 You seeks a rational estimate of the significance of conduct, and a standard by which it may be measured.

HUMAN'S NATURE

17 Moralists ancient and modern have had a good deal to say about the nature of human. To some of them it has seemed rather a simple thing to describe it. 18 Its constitution, as they have conceived it, has furnished them with certain principles which should guide human action. 19 Aristotle, who assumed that every human seeks own good, conceived of own good or "well-being" as largely identical with "well-doing." 20 This "well-doing" meant to him "fulfilling the proper functions of human," or in other words acting as the nature of human prescribes.

21 To the Stoic, human's duty was action in accordance with own nature. 22 Butler, many centuries later, found in human's nature a certain "constitution," with conscience naturally supreme and

the passions in a position of subordination. This "constitution" plainly indicated to him the conduct appropriate to a human being.

23 Such appeals to human's nature we are apt to listen to with a good deal of sympathy. Manifestly, human differs from the brutes, and they differ, in their kind, from each other. To each kind, a life of a certain sort seems appropriate. 24 The rational being is expected to act rationally, to some degree, at least. In our dealings with creatures on a lower plane, we pitch our expectations much lower. 25 And the behaviour we expect from each is that appropriate to its kind. The bee and the ant follow unswervingly their own law, and live their own complicated community life. 26 However the behaviour of the brute may vary in the presence of varying conditions, the degree of the variation seems to be determined by rather narrow limits. 27 These we recognise as the limits of the nature of the creature. It dictates to itself, unconsciously, its own law of action, and it follows that law simply and without revolt.

28 When we turn to human, "the crown and glory of the universe," as Darwin calls you, we find you, too, endowed with a certain nature in an analogous sense of the word. 29 You have capacities for which we look in vain elsewhere. The type of conduct we expect of you has its root in these capacities. 30 Human nature can definitely be expected to express itself in a human life,-- one lower or higher, but, in every case, distinguishable from the life of the brute. 31 It means something to speak of the physical and mental constitution of human, that mysterious reservoir from which your emotions and actions are supposed to flow. 32 We feel that we have a right to use the expression, even while admitting that the brain of human is, as far as psychology is concerned, almost unexplored territory, 33 and that the relation of mind to brain is, and is long likely to remain, a subject of dispute with philosophers and psychologists.

HOW TO DISCOVER HUMAN'S NATURE?

34 Nevertheless, in speaking of the nature of any living creature, we are forced to remind ourselves that the original endowment of the creature studied can never be isolated and subjected to inspection independently of the setting in which the subject of our study is found. 35 Who, by an examination of the brain of a bee or of an ant, could foresee the intricate organised industry of the hive or the anthill? 36 The seven ages of human are not stored ready-made in the little body of the infant. At any rate, they are beyond the reach of the most penetrating vision. 37 In the case of the simple mechanisms which can be constructed by human a forecast of future function is possible on the basis of a general knowledge of mechanics. But there is no living being of whose internal constitution we have a similar knowledge. 38 From the behaviour of the creature we gather a knowledge of its nature; we do not start with its nature as directly revealed and infer its behaviour. 39 That there are differences in the internal constitution of beings which react to the same environment in different ways, we have every reason to believe. 40 What those differences are in detail we cannot know. And our knowledge of the capacities inherent in this or that constitution will be limited by what we can observe of its reaction to environment.

41 Sometimes the reaction to environment is relatively simple and uniform. In this case we feel that we can attain without great difficulty to what may be regarded as a satisfactory knowledge of the nature of the creature studied. 42 The conception of that nature appears to be rather definite and unequivocal. When it is once attained, we speak with some assurance of the way in which the creature will act in this situation or in that. 43 If, however, the capacities are vastly more ample, and the environment to which this creature is adjusted is greatly extended, the difficulty of describing in any unequivocal way the nature of the creature becomes indefinitely greater.

44 Is it possible to contemplate human without being struck with the breadth and depth of the gulf which separates the primitive human being from the finished product of civilisation? 45 What a difference in range of emotion, in reach of intellect, in stored information, in freedom of action, between human at your lowest and human at your highest! 46 Can we describe in the same terms what is natural to human everywhere and always?

47 For the filthy and ignorant savage, absorbed in satisfying own immediate bodily needs, standing in the simplest of social relations, taking literally no thought for the morrow, 48 profoundly ignorant of the world in which you finds yourself, possessing over Nature no control worthy of the name, the sport and slave of your environment, it is natural to act in one way. 49 For enlightened humanity, acquainted with the past and forecasting the future, developed in intellect and refined in feeling, rich in the possession of arts and sciences, 50 intelligently controlling and directing the forces of Nature, socially organised in highly complicated ways, it is natural to act in another way. 51 And to each of the intermediate stages in the evolution of civilisation some type of conduct appears to be appropriate and natural.

52 Whither, then, shall we turn for our conception of human's nature? Shall we merely draw up a list of the instincts and impulses which may be observable in all humans? 53 Shall we say no more than that person is gifted with an intelligence superior to that of the brutes? 54 To do this is, to be sure, to give some vague indication of human's original endowment. But it can give us little indication of what it is possible for human, 55 with such an endowment, and in such an environment as makes own setting, to become. And what human becomes, that you are.

56 If human's nature can be revealed only through the development of own capacities, it is futile to seek it in a return to undeveloped human. 57 The nature of the chicken is not best revealed in the egg. And, as human can develop only in interaction with own environment, we must, to

understand you, study your environment also.

THE STRUGGLE WITH NATURE

George Stuart Fullerton

13 It is not possible to disentangle from each other and to consider quite separately the diverse elements which enter into the environment of human and which influence your development.

2 Your environment is two-fold, material and social; but your material setting may affect your social relations, and it is social human, not the individual as such, that achieves a conquest over Nature. 3 However, it is possible, and it is convenient, to direct attention successively upon the one and the other aspect of your environment.

4 At every stage of your development, human must have food, shelter, some means of defense. If they are not easily obtainable, you must strain every nerve to attain them. 5 Are your powers feeble and your intelligence undeveloped, it may tax all your efforts to keep yourself alive and to continue the race in any fashion. 6 The rules which determine your conduct seem rather the dictates of a stern necessity than the products of anything resembling free choice.

7 You who is lashed by hunger and haunted by fear, who cannot provide for the remote future, but must accept good or ill fortune as the accident of the day precipitates your lot upon you, lives and must live a life at but one remove from that of the brute. 8 In such a life the instincts of human attain to a certain expression, but intelligence plays a feeble part. The person remains a slave, under dictation, and moved by the dread of immediate disaster. 9 For an interest in what is remote in time and place, for the extension of knowledge for its own sake, for the development of activities which have no direct bearing upon the problem of keeping you alive and fed, there can be little place. 10 One must be assured that one can live, and live in reasonable security and physical well-being, before the problem of enriching and embellishing life can fairly

present itself as an important problem. 11 One must be set free before one can deliberately set out to shape one's life after an ideal.

12 Not that a severe struggle with physical Nature is necessarily and of itself a curse. It may call out human's powers, stimulate to action, and result in growth and development. 13 Where a prodigal nature amply provides for human's bodily necessities without much effort on your part, the result may be, in the absence of other stimulating influences giving rise to new wants, a paralysing slothfullness, an animal passivity and content. 14 This may be observed in whole peoples highly favoured by soil and climate, and protected by their situation from external dangers. 15 It may be observed in certain favoured classes even in communities which, by long and strenuous effort, have conquered Nature and raised themselves high in the scale of civilisation. 16 The idle sons of the rich, relieved from the spur of necessity, may undergo the degeneration appropriate to parasitic life. 17 In the midst of a strenuous activity adapted to call out the best intellectual and moral powers of human, they may remain unaffected by it, incapable of effort, unintelligent, slothful, the weak and passive recipients of what is brought to them by the labour of others.

18 But the struggle with physical Nature, sometimes a spur to progress and issuing in triumph, may also issue in defeat. 19 Nature may be too strong for human, or, at least, for human at an early stage of your development. She may thwart your efforts and dwarf your life. 20 It was through no accident that the Athenian state rose and flourished upon the shores of the Aegean; no such efflorescence of civilisation could be looked for among the Esquimaux of the frozen North.

THE CONQUESTS OF THE MIND

21 Physical environment counts for much, but the physical environment of human is the same as that of the creatures below you who seem incapable of progress. 22 It is as an intelligent being that you succeeds in bringing about

ever new and more complicated adjustments to your environment.
23 From the point of view of your animal life in many respects inferior to other creatures-- less strong, less swift, less adequately provided with natural means of defense, 24 less protected by Nature against cold, heat and the inclemencies of the weather, endowed with instincts less unerring, less prolific, through a long period of infancy helpless and dependent-- human nevertheless survives and prospers.
25 You have conquered the strong, overtaken the swift, called upon your ingenuity to furnish you with means of defence. 26 You have defied cold and heat, and we find you, with appliances of your own devising, successfully combating the rigours of Arctic frosts and the torrid sun of the tropics. 27 Intelligence has supplemented instinct and has guaranteed the survival of the individual and of the race.
28 It has even protected human against the self, against the very dangers arising out of your immunity from other dangers. 29 A gregarious creature, increasing and multiplying, you would be threatened with starvation did not your intelligent control over Nature furnish you with a food-supply which makes it possible for vast numbers of human beings to live and thrive on a territory of limited extent. 30 Moreover, you have compassed those complicated forms of social organisation which reveal themselves in cities and states, solving problems of production, transportation and distribution before which undeveloped human would stand helpless.
31 And from the problem of living at all you have passed to that of living well. You have created new wants and has satisfied them. 32 You have built up for yourself a rich and diversified life, many of the activities of which appear to have the remotest of bearings upon the mere struggle for existence, but the exercise of which gives you satisfaction. 33 Thus, the primitive instinct of curiosity, once relatively aimless and insignificant, has developed into the passion for systematic knowledge and the persistent search for truth; 34 the rudimentary

aesthetic feeling which is revealed in primitive human, and traces of which are recognisable in creatures far lower in the scale, has blossomed out in those elaborate creations, 35 which, at an enormous expense of labour and ingenuity, have come to enrich the domains of literature, music, painting, sculpture, architecture. 36 Civilised human is to a great extent occupied with the production of what you does not need, if need be measured by what your wants are at a lower stage of your development. 37 But these same things you needs imperatively, if we measure your need by your desires when they have been multiplied and their scope indefinitely widened.

THE CONQUEST OF NATURE AND THE WELL-BEING OF HUMAN

38 It is evident that the successful exploitation of the resources of material Nature is of enormous significance to the life of human. It may bring emancipation; it offers opportunity. 39 One is tempted to affirm, without stopping to reflect, that the development of the arts and sciences, the increase of wealth and of knowledge, must in the nature of things increase human happiness.

40 One is tempted, further, to maintain that an advance in civilisation must imply an advance in moralisation. 41 Human has a moral nature which exhibits itself to some degree at every stage of your development. 42 What more natural to conclude than that, with the progressive unfolding of your intelligence, with increase in knowledge, 43 with some relaxation of the struggle for existence which pits human against own fellow-human, and subordinates all other considerations to the inexorable law of self-preservation, 44 your moral nature would have the opportunity to show itself in a fuller measure?

45 When we compare human at your very lowest with human at your highest such judgments appear to be justified. But human is to be found at all sorts of intermediate stages.

46 Your knowledge may be limited, the development of the

arts not far advanced, your control over Nature far from complete, and yet you may live in comparative security and with such wants as you has reasonably well satisfied. 47 Your competition with your fellows may not be bitter and absorbing. 48 The simple life is not necessarily an unhappy life, if the simplicity which characterises it be not too extreme. 49 In judging broadly of the significance for human life of the control over Nature which is implied in the advance of civilisation, one must take into consideration several points of capital importance:

50 (1) The multiplication of human's wants results, not in happiness, but in unhappiness, unless the satisfaction of those wants can be adequately provided for.

51 (2) The effort to satisfy the new wants which have been called into being may be accompanied by an enormous expenditure of effort. 52 Where the effort is excessive human becomes again the slave of own environment. Your task is set for you, and you fulfills it under the lash of an imperious necessity. The higher standard may become as inexorable a task-master as was the lower.

53 (3) It does not follow that, because a given community is set free from the bondage of the daily anxiety touching the problem of living at all, and may address itself deliberately to the problem of living well, 54 it will necessarily take up into its ideal of what constitutes living well all those goods upon which developed human is apt to set a value. 55 A civilisation may be a grossly material one, even when endowed with no little wealth. With wealth comes the opportunity for the development of the arts which embellish life, but that opportunity may not be embraced.

56 Human may be materially rich and spiritually poor; you may allow some of your faculties to lie dormant, and may lose the enjoyments which would have been yours had they been developed. 57 The Athenian citizen two millenniums ago had no such mastery over the forces of Nature as we possess today.

58 Nevertheless, you was enabled to live a many-sided life beside

which the life of the modern human may appear poor and bare. 59 It is by no means self-evident that the good of human consists in the multitude of the material things which you can compel to your service.
